Configure the number of interrupt intervals for writing lines into CBUFF for the two RSZ engines.	RSZ_IRQ_RZA[12:0] RZA RSZ_IRQ_RZB[12:0] RZB	0x-
Enable the RSZ module.	RSZ_SRC_EN[0] EN	0x1
Enable resizer engine A.	RZA_EN[0] EN	0x1
Enable resizer engine B.	RZB_EN[0] EN	0x1

NOTE: RSZ-A or RSZ-B must be enabled after setting all needed configuration parameters.

8.3.4.4.1.3 ISS ISP RSZ Reset Behavior

Because the RSZ module has no software reset, software can issue one at the ISP level. Moreover, upon hardware reset, all the registers in the RSZ are reset to their reset values. Table 8-485 identifies the proper software sequence before and after RSZ reset issues at the ISP level.

Table 8-485. ISS ISP RSZ Reset Behavior

Step	Register/Bit Field/Programming Model	Value
ELSE IF: Is FIFO overflow or blanking error present?	ISP5_IRQSTATUS_i[18] RSZ_FIFO_IN_OVF or ISP5_IRQSTATUS_i[19] RSZ_FIFO_IN_BLK_ERR	= 0x1
Clear the FIFO blanking event.	ISP5_IRQENABLE_CLR_i[19] RSZ_FIFO_IN_BLK_ERR	0x1
Clear the overflow event.	ISP5_IRQENABLE_CLR_i[18] RSZ_FIFO_IN_OVF	0x1
ELSE: No FIFO overflow or blanking error is present?		
Wait until there is no DMA process and the module ready for reset.	ISP5_SYSCONFIG[1] SOFTRESET and ISP5_IRQSTATUS_i[15] RSZ_INT_DMA	= 0x0
ENDIF		
Disable the source data.	RSZ_SRC_EN[0] EN	0x0
Reset the RSZ at the ISP level.	ISP5_SYSCONFIG[1] SOFTRESET	0x1
Check whether the RSZ has been reset properly.	ISP5_SYSCONFIG[1] SOFTRESET	0x-

8.3.4.4.2 ISS ISP RSZ Global Image Processing Settings

This section discusses the configuration of the RSZ global settings before and during image frame processing. Table 8-486 identifies the global RSZ functional sequence, which includes global control, frame settings, bandwidth control, and reversal output image frames.

Table 8-486. ISS ISP RSZ Global Image Processing Settings

Step	Register/Bit Field/Programming Model	Value
Initialize the RSZ module.	See Section 8.3.4.4.1.	
Determine input data type and configure the source parameters.	See Section 8.3.4.4.2.1.	
Determine if vertical flip of the output image will be performed by the two resizer engines and set accordingly.	RSZ_SEQ[1] VRVA	0x-
	RSZ_SEQ[3] VRVB	

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 8-486. ISS ISP RSZ Global Image Processing Settings (continued)

Step	Register/Bit Field/Programming Model	Value
Determine if horizontal flip of the output image will be performed by the two resizer engines and set accordingly.	RSZ_SEQ[0] HRVA	0x-
	RSZ_SEQ[2] HRVB	
Set the baseline address of the RSZ output to CBUFF. Best performance can be achieved by assigning address on a 128-byte boundary.	RZA_SDR_Y_BAD_H[15:0] Y_BAD_H	0x-
	RZA_SDR_Y_BAD_L[15:0] Y_BAD_L	
	RZB_SDR_Y_BAD_H[15:0] Y_BAD_H	
	RZB_SDR_Y_BAD_L[15:0] Y_BAD_L	
	RZA_SDR_C_BAD_H[15:0] C_BAD_H	
	RZA_SDR_C_BAD_L[15:0] C_BAD_L	
	RZB_SDR_C_BAD_H[15:0] C_BAD_H	
	RZB_SDR_C_BAD_L[15:0] C_BAD_L	
Set the start address of the RSZ output to CBUFF. The first data output will be written to this address. If the first line of a frame is written at the beginning of the CBUFF memory, then SAD = BAD and PTR_S = 0. It is strongly advised to set up this address on a 128-byte boundary, which leads to the best performance.	RZA_SDR_Y_SAD_H[15:0] Y_SAD_H	0x-
	RZA_SDR_Y_SAD_L[15:0] Y_SAD_L	
	RZB_SDR_Y_SAD_H[15:0] Y_SAD_H	
	RZB_SDR_Y_SAD_L[15:0] Y_SAD_L	
	RZA_SDR_C_SAD_H[15:0] C_SAD_H	
	RZA_SDR_C_SAD_L [15:0] C_SAD_L	
	RZB_SDR_C_SAD_H[15:0] C_SAD_H	
	RZB_SDR_C_SAD_L[15:0] C_SAD_L	
Set the start pointer of the CBUFF internal counter. It must be set up as PTR_S = (SAD – BAD) / OFT. PTR_S is expressed in number of lines.	RZA_SDR_Y_PTR_S[12:0] Y_PTR_S	0x-
	RZB_SDR_Y_PTR_S[12:0] Y_PTR_S	
	RZA_SDR_C_PTR_S[12:0] C_PTR_S	
	RZB_SDR_C_PTR_S[12:0] C_PTR_S	
Set the end pointer of the CBUFF internal counter. PTR_E is expressed in number of lines. The CBUFF can contain up to PTR_E lines.	RZA_SDR_Y_PTR_E[12:0] Y_PTR_E	0x-
	RZB_SDR_Y_PTR_E[12:0] Y_PTR_E	
	RZA_SDR_C_PTR_E[12:0] C_PTR_E	
	RZB_SDR_C_PTR_E[12:0] C_PTR_E	
Set the line of offset expressed in bytes between two lines in the CBUFF (Line 0 = SAD, Line 1 = SAD + 1 x OFT, Line 2 = SAD + 2 x OFT). PTR_E is expressed in number of lines. The CBUFF can contain up to PTR_E lines. Note: OFT does not necessarily correspond to the size of a line in a frame; it can be much bigger. The line offset must be a multiple of 128 bytes.	RZA_SDR_Y_OFT[16:0] Y_OFT	0x-
	RZB_SDR_Y_OFT[16:0] Y_OFT	
	RZA_SDR_C_OFT[16:0] C_OFT	

PRELIMINARY

Table 8-486. ISS ISP RSZ Global Image Processing Settings (continued)

Step	Register/Bit Field/Programming Model	Value
	RZB_SDR_C_OFT[16:0] C_OFT	
Determine output data type, whether it will be flipped, and configure the output memory addresses.	See Section 8.3.4.4.2.2.	

NOTE: When data output is 4:2:2 or 4:2:0-Y only, the following values are not needed:

- RZx_SDR_C_BAD_x
- RZx_SDR_C_SAD_x
- RZx_SDR_C_PTR_S
- RZx_SDR_C_PTR_E
- RZx_SDR_C_OFT

When output is 4:2:0-C only, the following values are not needed:

- RZx_SDR_Y_BAD_x
- RZx_SDR_Y_SAD_x
- RZx_SDR_Y_PTR_S
- RZx_SDR_Y_PTR_E
- RZx_SDR_Y_OFT

8.3.4.4.2.1 ISS ISP RSZ Global Image Processing Settings – Subsequence 1

The procedure shown in Figure 8-252 determines which of the RSZ engines is enabled and the type of input data, and configures the source data parameters.

8.3.4.4.4 ISS ISP RSZ Programming Constraints

The RSZ module contains shadowed and nonshadowed registers. Shadowed registers can be updated anytime during the resizing operation, but the new setting does not take effect until the next rsz_int_reg event. Shadowed registers can be updated for the next frame after the rsz_int_reg event triggers.

Nonshadowed registers must be programmed before enabling the RSZ module or between frames (that is, after the rsz_int_dma and the entire frame have come on the VPORT interface, and before the VD of the next frame). Table 8-492 lists the nonshadowed registers.

8.3.4.5 ISS ISP H3A Programming Model

This section discusses issues related to the software control of the H3A module. It lists the registers that must be programmed in different modes, how to enable and disable the H3A, how to check the status of the H3A, discusses the different register access types, and enumerates several programming constraints.

8.3.4.5.1 ISS ISP H3A Hardware Setup/Initialization

This section discusses the configuration of the H3A required before image processing can begin.

8.3.4.5.1.1 ISS ISP H3A Reset Behavior

Upon hardware reset of the ISP, all the registers in the H3A are reset to their reset values.

8.3.4.5.1.2 ISS ISP H3A Register Setup

For register configuration purposes, the AF and AEW engines of the H3A can be configured independently. Because there are separate enable bits for each engine, this section is divided into the AF engine and the AEW engine.

8.3.4.5.1.2.1 ISS ISP H3A AF Engine

Before enabling the AF engine, the hardware must be properly configured through register writes. Table 8-493 lists the register parameters that must be programmed before enabling the AF engine of the H3A.

8.3.4.5.2 ISS ISP H3A Enable/Disable Hardware

Setting the H3A_PCR[0] AF_EN bit enables the AF engine, and setting the H3A_PCR[16] AEW_EN bit enables the AEW engine. This is done after all of the required registers discussed in the previous section are programmed.

The H3A operates in continuous mode. Processing of the frame is dependent on the timing of the IPIPEIF. To ensure that data from the IPIPEIF is not missed, the H3A must be enabled before the IPIPEIF. In this way, the H3A waits for data from the IPIPEIF. The AF engine or the AEW engine can be disabled by clearing the H3A_PCR[0] AF_EN or H3A_PCR[16] AEW_EN bit, respectively, during the processing of the last frame. The disable is latched in at the end of the frame in which it was written.

8.3.4.5.3 ISS ISP H3A Register Accessibility During Frame Processing

There are two types of register accesses in the H3A module:

- Shadow registers

  These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads still return the most-recent write even though the settings are not used until the next start of frame.

  The only shadowed registers in the H3A module are:

  – H3A_AFPAX1
  – H3A_AFPAX2
  – H3A_AFPAXSTART
  – H3A_AFIIRSH
  – H3A_AEWWIN1
  – H3A_AEWINSTART
  – H3A_AEWINBLK
  – H3A_AEWSUBWIN
  – H3A_AEWCFG
  – H3A_AEWBUFST

- Busy-lock registers

  All other registers, except those described previously, belong to this category.

  Busy-lock registers cannot be written when the module is busy (H3A_PCR[15] BUSYAF == 1 or H3A_PCR[18] BUSYAEAWB == 1). Writes are allowed to occur, but no change occurs in the registers (blocked writes from the hardware perspective, but allowed write from the software perspective). Once the busy bit in the H3A_PCR register (H3A_PCR[15] BUSYAF or H3A_PCR[18] BUSYAEAWB bit) is reset to 0, the busy-lock registers can be written.

The ideal procedure for changing the H3A registers if (H3A_PCR[15] BUSYAF == 0 or H3A_PCR[18] BUSYAEAWB == 0) or if (EOF interrupt occurs) is:

1. Disable AF or AE/AWB.
2. Change registers.
3. Enable AF or AE/AWB.

8.3.4.5.4 ISS ISP H3A Interframe Operations

Between frames, it may be necessary to modify the memory pointers before processing the next frame. Because the H3A_PCR register and memory pointer registers are shadowed, these modifications can take place any time before the end of the frame, and the data will be latched in for the next frame. The host controller can perform these changes upon receiving an interrupt.

8.3.4.5.5 ISS ISP H3A Summary of Constraints

Adhere to the following list of register configuration constraints when programming the H3A. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

- The output addresses (H3A_AFBUFST[31:5] AFBUFST) must be on 64-byte boundaries.
- Each horizontal row of paxels () or windows () starts on a 32-byte boundary.
- If the pixel clock frequency is less than ISP_FCLK / 2 and vertical focus is enabled, the constraints listed in Table 8-495 apply.

Table 8-495. ISS ISP H3A Constraints When PCLK < ISP_FCLK / 2 and Vertical Focus Enabled

Field	Constraint
H3A_AEWWIN1[20:13] WINW	>7
H3A_AFPAX1[23:16] PAXW	>7
H3A_AFIIRSH[11:0] IIRSH	None
H3A_AFPAXSTART[27:16] PAXSH	>= H3A_AFIIRSH[11:0] IIRSH + 2
H3A_AFPAX2[20:17] AFINCH	None
H3A_AFPAX2[5:0] PAXHC	<=11

- If the pixel clock frequency is less than ISP_FCLK / 2 and vertical focus is disabled, the constraints listed in Table 8-496 apply.

Table 8-498. ISS ISP H3A Constraints When PCLK >= ISP_FCLK / 2 and Vertical Focus Disabled (continued)

Field	Constraint
H3A_AFPAX2[5:0] PAXHC	<= 35

AF engine

- The paxel horizontal start value must be greater than or equal to the IIR horizontal start position.
- The paxel start/end and IIR filter start positions must not be set within the first 2 and the last 2 pixels (to check).
- The width (H3A_AFPAX1[23:16] PAXW) and height (H3A_AFPAX1[7:0] PAXH) of the paxels must be an even number.
- The minimum width of the paxel (H3A_AFPAX1[23:16] PAXW) must be 16 pixels, if pixel clock is half or less of the ISP_FCLK clock. If pixel clock is equal to ISP_FCLK, then the minimum width is 32 pixels.
- The value of H3A_AFPAX2[20:17] AFINCH bit-field should be higher than 0, irrespective of the ratio of the pixel clock to the ISP_FCLK.
- The number of columns to increment in a paxel (H3A_AFPAX2[20:17] AFINCH) must be even and is restricted to 2 to 32.
- The number of lines to increment in a paxel (H3A_AFPAX2[16:13] AFINCV) must be even and is restricted to 0 to 30.
- The maximum number of vertical paxels in a frame (H3A_AFPAX2[12:6] PAXVC) must not exceed 128.
- The number of paxels in the horizontal direction (H3A_AFPAX2[5:0] PAXHC) has a valid range from 1 to 35.
- If vertical mode is enabled:
  - The paxel horizontal start position (H3A_AFPAXSTART[27:16] PAXSH) must be even.
  - The lower bit of the H3A_AFPAXSTART[27:16] PAXSH bit field and the lower bit of the H3A_AFIIRSH[11:0] IIRSH bit field must be equal.
  - The H3A_AFPAXSTART[11:0] PAXSV bit field must be >= 8.
- If vertical mode is not enabled, the H3A_AFIIRSH[11:0] IIRSH bit field must be even.
- Paxels cannot overlap the last pixel in a line.
- Paxels must be adjacent to one another.

AEW engine

- The width (H3A_AEWWIN1[20:13] WINW) and height (H3A_AEWWIN1[31:24] WINH) of the windows must be an even number.
- The minimum width of the window (H3A_AEWWIN1[20:13] WINW) must be 16 pixels, if the pixel clock is half or less of the ISP_FCLK clock. If the pixel clock is equal to ISP_FCLK, then the minimum width is 32 pixels.
- The window height (H3A_AEWWIN1[31:24] WINH) has a valid range from 2 to 512.
- The maximum number of vertical windows in a frame (H3A_AEWWIN1[12:6] WINVC) must not exceed 128.
- The number of horizontal windows (H3A_AEWWIN1[5:0] WINHC) has a valid range from 1 to 35.
- The vertical and horizontal window start position (H3A_AEWWINSTART) has a valid range from 0 to 4095.
- The vertical window start position for single black lines (H3A_AEWINBLK[27:16] WINSV) has a valid range from 0 to 4095.
- The horizontal window start position for single black lines (H3A_AEWINBLK[6:0] WINH) must be even and has a valid range from 2 to 256.
- The subsampling windows can start only on even numbers.

5:4	STANDBYMODE	Configuration of the local initiator state management mode. By definition, initiator may generate read/write transaction as long as it is out of STANDBY state. 0x0: Force-standby mode: local initiator is unconditionally placed in standby state. Backup mode, for debug only. 0x1: No-standby mode: local initiator is unconditionally placed out of standby state. Backup mode, for debug only. 0x3: Reserved 0x2: Smart-standby mode: local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. IP module must not generate (initiator-related) wake-up events. Generation of the MStandby signal must be initiated by the firmware by writing ISP5_CTRL.MSTANDBY = 1.	RW	0x2
3:2	RESERVED		R	0x0

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
1	SOFTRESET	Software reset. The soft reset will cause the MStandby to be asserted as the reset value of the ISP5_CTRL.MSTANDBY bit is 1. After a soft reset, the software must ensure not to perform any access for 16 clock cycles (OCP-slave port frequency) after writing this bit. The OCP slave port is running at half the frequency of the functional clock. Before issuing a soft reset, the software must ensure that no more traffic is being generated by the ISP. Basically, it means that the camera module must be stopped from sending data and/or that the ISP modules are disabled. The last interrupt triggered by the ISP design upon completion of the frame processing is rsz_int_dma. This rsz_int_dma event must be used to enable clean termination of the processing. The software must wait a few hundred cycles to trigger the soft reset after upon assertion of the rsz_int_dma, this is to ensure that the BL is completely drained. Software must set the ISP in standby mode before issuing the soft reset: Set ISP5_SYSCONFIG.STANDBYMODE = 2 (smart standby). Set ISP5_CTRL.MSTANDBY to 1. Poll for ISP5_CTRL.MSTANDBY_WAIT = 1. Then, the soft reset can be applied (ISP5_SYSCONFIG.SOFTRESET = 1). Write 0x0: No action Write 0x1: Initiate software reset Read 0x1: Reset (software or other) ongoing Read 0x0: Reset done, no pending action	RW	0
0	AUTO_IDLE	Auto clock gating. Always enabled.	R	1

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
19	RSZ_FIFO_IN_BLK_ERR	This event signals that the minimum vertical blanking period has not been respected causing errors in the input data buffering submodule. This event will be triggered when the rsz_int_reg event of frame N is triggered before the rsz_int_dma of frame N + 1. This event would typically happen at the transition between two frames because there is not enough vertical blanking between frames: the firmware must take care to ensure enough vertical blanking. The hardware cannot recover from this error. It will be required to perform a reset of the IP. Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending	RW W1toSet	0
18	RSZ_FIFO_OVF	This event signals that overflow happened in the input data buffering submodule. This event would typically happen while processing a frame because the video port pixel clock is too high: the firmware must take care to use a lower pixel clock at the input of the resizer module. Depending on the mode being used, the overflow can happen at different places: 1. Bypass mode: overflow happened in the input circular buffer. 2. Pass through mode: overflow happened on the module output interface (MTC) 3. Normal resize mode: overflow happened in the input circular buffer. The hardware cannot recover from this error. It will be required to perform a reset of the IP. Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending	RW W1toSet	0
17	RSZ_INT_CYC_RZB	RESIZER module event: This event is the circular interrupt for RESIZER #B. An event can be triggered every time that RSZ_IRQ_RZB output lines have been written out to the RZB_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, this value should be such that the circular buffer vertical size (set by the RZB_SDR_Y_PTR_E register) is a multiple of RSZ_IRQ_RZB. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first. Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending	RW W1toSet	0

PRELIMINARY

Table 8-512. ISP5_IRQSTATUS_i

Address Offset	0x0000 0028 + (0x10 * i)	**Index**	i = 0 to 3
Physical Address	0x5201 0028 + (0x10 * i)	**Instance**	ISS_ISP5_SYS1
Description	Per-event "enabled" interrupt status vector. Enabled status is not set unless event is enabled. Write 1 to clear the status after interrupt has been serviced (raw status gets cleared, that is, even if not enabled). The ISP outputs four interrupt lines, ISP_IRQ0 to ISP_IRQ3. Any internal ISP event can be merged on the four lines. A same event must be enabled on only one interrupt line.		
Type	RW

Bits	Field Name	Description	Type	Reset
23	RSZ_INT_EOF1	RESIZER module event: This event signals that the BL has received the EOF signal from the resizer B engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
22	RSZ_INT_EOF0	RESIZER module event: This event signals that the BL has received the EOF signal from the resizer A engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
21:20	RESERVED		R	0x0
19	RSZ_FIFO_IN_BLK_ERR	This event signals that the minimum vertical blanking period has not been respected causing errors in the input data buffering submodule. This event will be triggered when the rsz_int_reg event of frame N is triggered before the rsz_int_dma of frame N + 1. This event would typically happen at the transition between two frames because there is not enough vertical blanking between frames: the firmware must take care to ensure enough vertical blanking. The hardware cannot recover from this error. It will be required to perform a reset of the IP. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
18	RSZ_FIFO_OVF	This event signals that overflow happened in the input data buffering submodule or in the RSZ output interface. This event would typically happen while processing a frame because the video port pixel clock is too high: the firmware must take care to use a lower pixel clock at the input of the resizer module. The hardware cannot recover from this error. It will be required to perform a reset of the IP. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
17	RSZ_INT_CYC_RZB	RESIZER module event: This event is the circular interrupt for RESIZER #B. An event can be triggered every time that RSZ_IRQ_RZB output lines have been written out to the RZB_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, this value should be such that the circular buffer vertical size (set by the RZB_SDR_Y_PTR_E register) is a multiple of RSZ_IRQ_RZB. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
16	RSZ_INT_CYC_RZA	RESIZER module event: This event is the circular interrupt for RESIZER #A. An event can be triggered every time that RSZ_IRQ_RZA output lines have been written out to the RZA_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, the circular buffer vertical size (set by the RZA_SDR_Y_PTR_E register) should be a multiple of RSZ_IRQ_RZA. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
15	RSZ_INT_DMA	This event is triggered when the last EOF (of the two MTC interfaces) is sent out to the BL and that the resizer core has returned to idle. rsz_int_dma is a true indication that all processing is finished for the particular frame on both resizer engines. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
14	RSZ_INT_LAST_PIX	This event is triggered when the last pixel of the valid area is received. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
13	RSZ_INT_REG	This event is triggered when the first pixel of the valid area is received. Shadowed registers can be updated at any time but the new value will take effect on the next rsz_int_reg event. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
22	RSZ_INT_EOF0	RESIZER module event: This event signals that the BL has received the EOF signal from the resizer A engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW	0
21:20	RESERVED		R	0x0
19	RSZ_FIFO_IN_BLK_ERR	This event signals that the minimum vertical blanking period has not been respected causing errors in the input data buffering submodule. This event will be triggered when the rsz_int_reg event of frame N is triggered before the rsz_int_dma of frame N + 1. This event would typically happen at the transition between two frames because there is not enough vertical blanking between frames: the firmware must take care to ensure enough vertical blanking. The hardware cannot recover from this error. It will be required to perform a reset of the IP. Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
18	RSZ_FIFO_OVF	RESIZER module event: This event signals that overflow happened in the input data buffering submodule or in the RSZ output interface.. This event would typically happen because the video port pixel clock is too high. Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
17	RSZ_INT_CYC_RZB	RESIZER module event: This event is the circular interrupt for RESIZER #B. An event can be triggered every time that RSZ_IRQ_RZB output lines have been written out to the RZB_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, this value should be such that the circular buffer vertical size (set by the RZB_SDR_Y_PTR_E register) is a multiple of RSZ_IRQ_RZB. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first. Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
31:30	DMA3_CFG	This bit field selects the DMA transfer configuration which is used with the ISS_DRE_4 DMA request signal. This DMA request is generated from IPIPE_INT_LAST_PIXEL event. One can choose to use this DMA request to transfer the DPC initialization data, the gamma table, or both. 0x0: No DMA request associated with ISS_DREQ_4. 0x1: DPC DMA request associated with ISS_DREQ_4. Expected DMA transfer size is 2 KiB in the range 0x8000-0x87FF. DPC_EVT_INI must be set to 0. 0x3: DPC + GAMMA DMA request associated with ISS_DREQ_4. Expected DMA transfer size is 8 KiB in the range 0x8000-0x87FF and 0xA800-0xBFFF. DPC_EVT_INI must be set to 0. 0x2: GAMMA DMA request associated with ISS_DREQ_4. Expected DMA transfer size is 6 KiB in the range 0xA800-0xBFFF.	RW	0x0
29:28	RESERVED		R	0x0
27	RESERVED		R	0x0
26	HST_RD_CHK	When the HISTOGRAM computation is enabled and the HST DMA request is not used to read out the data, this register ensures that the data is read fast enough, else an interrupt ISP5_IRQSTATUS2_i[5] IPIPE_HST_ERR is triggered. The hardware sets automatically this bit to 1 when software can start reading the memory.	RW	0

CAUTION

Software must set this bit to 0 after reading the data. Once the MPU/IPU has read the histogram data, it must clear this register, else the ISP5_IRQSTATUS2_i[5] IPIPE_HST_ERR will occur.

Write 0x0: Clears the signal to avoid error generation. The software must write this bit to 0 after the last data read.

Write 0x1: Reserved

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
		Read 0x1: The MPU/IPU can read the data from the memory. Needs to complete fast enough to avoid the interrupt generation.		
		Read 0x0: No interrupt generation can happen		
25	DPC_EVT_INI	Select the IPIPE module event to be used to generate the DMA requests for the DPC submodule. 0x0: IPIPE_INT_LAST_PIX event is selected. 0x1: IPIPE_INT_DPC_INI event is selected.	RW	0
24	MSTANDBY	MStandby signal assertion and de-assertion control for power management transitions. After software reset, this bit is asserted. Write "1" to transition from normal mode to idle mode. The firmware needs to ensure that no more ISP processing is ongoing before setting up this bit. Write "0" to transition from idle mode to normal mode. The software should poll ISP5_CTRL.MSTANDBY_WAIT = 0 after writing ISP5_CTRL.MSTANDBY = 0 in a transition from idle to normal mode. 0x0: De-assert MStandby signal. May not be immediate due to power management handshaking btw the MStandby and Wait signals. 0x1: Assert MStandby signal	RW	1
23	VD_PULSE_EXT	VD pulse extension enable This bit enables or disables the VD extension bridge. By default, the bridge is enabled. At ISS level, it is expected that ISP5_CTRL.VD_PULSE_EXT = 1 when the VPORT gets data from the CSI2 RX module and ISP5_CTRL.VD_PULSE_EXT = 0 when the VPORT gets data from the parallel interface or the CCP2 RX module. There must be at least three clock cycles between the time this bit is modified and the HD/VD pulse for start of frame comes. 0x0: Disabled 0x1: Enabled	RW	1
22	PCLK_INV	Pixel clock inversion This bit enables or disables pixel clock inversion. The ISP always samples the data on the rising edge of the pixel clock. Enabling the inversion shifts the resampling period by 1/2 a pixel clock period. PCLK needs to be disabled at ISS level before setting to 0x1 this bit. This can be done through the proper ISS_CLKCTRL[] VPORTx_CLK register bit on ISS top level, depending on the interface (CCP2 or CSI2) that is sending data on the ISP video port. 0x0: Normal 0x1: Inversed	RW	0
21	MFLAG	MFlag signal generation control This bit controls how the OCP MFlag signal is generated on the ISS NOC. 0x0: The MFlag value is dynamic. 0x1: The MFlag value is static. The value is set with the ISP5_CTRL[3:1] VBUSM_CPRIORITY.	RW	0
20	MSTANDBY_WAIT	MStandby / Wait power management status bit. The power management framework of the ISP is based on the handshaking of the MStandby and Wait signals. The software is not supposed to write inside the ISP slave port and initiate traffic when ISP5_CTRL.MSTANDBY bit is written. The software can poll this bit to know when Wait signal is deasserted. Read 0x1: MStandby signal is asserted. Read 0x0: MStandby signal is deasserted.	R	-
19:16	RESERVED		R	0x0

Table 8-530. ISP5_BL_VBUSM

Address Offset	0x0000 0088		
Physical Address	0x5201 0088	**Instance**	ISS_ISP5_SYS1
Description	BL VBUSM TUNING REGISTER The settings in the register are static and not expected to be modified dynamically.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																										MFLAG_THRES	LASTCMD_DLY				

Bits	Field Name	Description	Type	Reset
31:6	RESERVED		R	0x0000000
5	MFLAG_THRES	MFLAG Threshold value The value of this bit field is a threshold which is compared to the MFlag output of the ISP5. If the BL MFlag signal is greater or equal to this threshold the last beat of the VBUSM command is delayed by ISP5_BL_VBUSM[4:0] LASTCMD_DLY cycles. Only values 0, 1 are valid, the least significant bit is tied off to 1 to make a 2-bit field. 0x0: Thres = 1 0x1: Thres = 3	RW	1
4:0	LASTCMD_DLY	The value of this bit field represents a delay expressed in cycles (L3_MAIN clock). This value is used to delay the last beat of the VBUSM command such that the ISP does not loose arbitration at the ISS level because the BL does not generate back to back requests by default. The last beat is delayed until the counter expires or the new request is accepted. This delay is used when the MFlag output of the ISP is greater or equal to ISP5_BL_VBUSM[5] MFLAG_THRES. One can set this value to 0 to disable the last command beat delay.	RW	0x04

Address Offset	0x0000 0024 + (0x10 * i)	**Index**	i = 0 to 3
Physical Address	0x5201 00C4 + (0x10 * i)	**Instance**	ISS_ISP5_SYS2
Description	Per-event interrupt enable bit vector. Write 1 to clear (disable interrupt). Readout equal to corresponding _SET register. Overflow / underflow errors are not recoverable at ISP level, a software reset is required at ISS level. The ISP outputs 4 interrupt lines ISP5_IRQ0 to ISP5_IRQ3. Any internal ISP event can be merged on the 4 lines. A same event must be enabled on only one interrupt line.		
Type	RW

RESERVED																															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:0	RSZ_FRACDIV	Fractional clock divider value. The fractional clock divider gates the read requests made to the input data buffer such that the input data buffer is read at an average frequency equal to FFCLK instead of FCLK. The value of FFCLK depends upon the upscaling ratios as well as the input pixel clock: We have FFCLK = FCLK / FRACDIV MHz and RSZ_FRACDIV = 65536 / FRACDIV. When RSZ_ FRACDIV = 65536, we have: FFCLK = FCLK.	RW	0xFFFF

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:0	HPS	Horizontal Start Position The RSZ_SRC_HPS register has two functions: The first function is to compensate for possible delay between the HD pulse and the first valid data. It is possible for this delay to be different than 0 when the RESIZER module gets its input data from the VP connected to the IPIPEIF module (the offset value can be odd or even). When data are coming from the IPIPE module, it is not required to resynchronize HD and the first valid data. The second function is to crop the data in the horizontal direction. When used for cropping, only RSZ_SRC_HPS must be even or null.	RW	0x0000

Table 8-620. RZA_V_PHS_Y

Address Offset	0x0000 0094		
Physical Address	0x5201 0494	**Instance**	ISS_RESIZER
Description	RESIZER A - INITIAL LUMINANCE PHASE OF VERTICAL RESIZING PROCESS When YUV4:2:2 data are output, the phase values for luma and chroma should typically be equal, that is, RZX_V_PHS_Y= RZX_V_PHS_C. The following constraints apply when setting the initial vertical phases ABS(RZX_V_PHS_Y - RZX_V_PHS_C) RZX_V_DIF. This constraint means that at most the distance between the initial phases for luminance and chrominance is not expected to exceed the distance between two luma pixels. Note that the absolute value is used, hence, the initial luma phase can be greater than the initial chroma phase or the other way around. As a reminder, the distance between two output pixels for luma is given by RZX_V_DIF.

Table 8-692. RZB_V_PHS_Y

Address Offset	0x0000 0124		
Physical Address	0x5201 0524	**Instance**	ISS_RESIZER
Description	RESIZER B - INITIAL LUMINANCE PHASE OF VERTICAL RESIZING PROCESS When YUV4:2:2 data are output, the phase values for luma and chroma should typically be equal, that is, RZX_V_PHS_Y= RZX_V_PHS_C. The following constraints apply when setting the initial vertical phases ABS(RZX_V_PHS_Y - RZX_V_PHS_C) RZX_V_DIF. This constraint means that at most the distance between the initial phases for luminance and chrominance is not expected to exceed the distance between two luma pixels. Note that the absolute value is used, hence, the initial luma phase can be greater than the initial chroma phase or the other way around. As a reminder, the distance between two output pixels for luma is given by RZX_V_DIF.

31:16	RESERVED		R	0x0000
15:5	RESERVED		R	0x000
4	VAL4	Status of Histogram Process (busy status).	R	0
3	VAL3	Status of Histogram bank select.	R	0
2	VAL2	Status of BSC process (busy status).	R	0
1	VAL1	Status of Boxcar process (busy status).	R	0
0	VAL0	Status of Boxcar process (error status). This bit will be triggered when an overflow happens while transferring the boxcar data to memory. Instead of polling for this register, it is preferable to use the IPIPE_BOXCAR_OVF interrupt. Overflow errors are non recoverable at ISP level and require a software reset at ISS level.	R	0

Table 8-911. IPIPE_YUV_PHS

Address Offset	0x0000 02C8		
Physical Address	0x5201 0AC8	**Instance**	ISS_IPIPE
Description	YUV4:2:2 down sampling register. This register controls the YUV4:4:4 to YUV4:2:2 chroma downsampling. This register is valid if IPIPE_SRC_FMT.FMT = 0 (RAW input and YUV output). IPIPE_YUV_PHS = 0 leads to pure subsampling, no filtering, cosited chroma output. IPIPE_YUV_PHS = 1 leads to (1, 1) >> 1 filtering, centered chroma output. IPIPE_YUV_PHS = 2 leads to (1, 2, 1) >> 1 filtering, cosited chroma output. IPIPE_YUV_PHS = 3 leads to (1, 3, 3, 1) >> 3 filtering, centered chroma output. When the chroma output is cosited, and that downsampling is enabled in the RESIZER module, one need to take care that the averager disrupts the relative phase for luma and chroma color components. The RZA_H_PHS_ADJ and RZB_H_PHS_ADJ registers need to be used to fix the disruption.		
Type	RW

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:2	RESERVED		R	0x0000
1	LPF	121-LPF enable for chrominance samples. This register is valid if IPIPE_SRC_FMT.FMT = 0 (RAW input and YUV output). 0x0: off 0x1: on	RW	0
0	POS	This bit sets the output position of the chrominance sample with regards to the luma sample positions. One can choose between centered and cosited. This register is valid if IPIPE_SRC_FMT.FMT = 0 (RAW input and YUV output). The RESIZER module does not change the relative position of the chroma samples vs. the luma samples between the input and output and the chroma position at the output of the IPIPE module and at the output of the RESIZER module must be identical. In other words, we must have RSZ_YUV_PHS.POS = IPIPE_YUV_PHS.POS. 0x0: Cosited = same position with luminance 0x1: Centered = middle of the luminance	RW	0

RESERVED																RESERVED														CLR	SEL

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:2	RESERVED		R	0x0000
1	CLR	Histogram memory clear. The histogram can be cleared before the start of operations. However, the clear takes 512 cycles and therefore: + if line size > 512, the first line must not be used for histogram computation. + if line size < 512, ceil (512/line size) lines must not be used for histogram computation. It's the programmer's responsibility to set the histogram computation area outside the "clear" area. 0x0: Disable 0x1: Enable	RW	0
0	SEL	This bit must be used to select which memory is used to store the histogram data. By selecting alternatively one or the other bit, one can double buffer the histogram output buffer. The 4-KiB memory can either be read by the CPU or a DMA request. 0x0: Use Table 0 and 1 = 4 KiB in the memory ISP map. 0x1: Use Table 2 and 3 = 4 KiB in the memory ISP map.	RW	0

8.3.5.6 ISS ISIF Registers

CAUTION

The ISS ISIF registers are limited to 32 bit and 16 bit data accesses; 8bit data access is not allowed and can corrupt register content.

Table 8-1012. ISIF_SYNCEN

Address Offset	0x0000 0000		
Physical Address	0x5201 1000	**Instance**	ISS_ISIF
Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																RESERVED														DWEN	SYEN

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:2	RESERVED		R	0x0000
1	DWEN	Controls the storage of image sensor RAW data in memory. This bit is loaded with the timing of the internal VD signal: it becomes active starting at the lead of the VD signal that comes after 1 is written in this bit. 0x0: Disable 0x1: Enable	RW	0
0	SYEN	Controls ON/OFF of VD/HD output. Internal timing generator becomes active and VD/HD output starts when 1 is written in this bit. In case of input, VD/HD loading begins. 0: Disable 1: Enable	RW	0

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x0000
15	MDFS	Field Status This bit indicates the status of the current FLD signal when the ISIF module is in interlaced mode. Read 0x1: Even field Read 0x0: Odd field	R	0
14	HLPF	Low pass filter enable. When this bit is enabled, a 3-tap (1/4 + 1/2 Z^{-2} + 1/4 Z^{4}) filtering process is performed on the sensor data. 0x0: Disable 0x1: Enable	RW	0
13:12	INPMOD	Data input mode: 0x0: RAW data 0x1: YCbCr 16bit 0x3: Reserved 0x2: YCbCr 8bit	RW	0x2
11	OVF	ISIF module write port overflow status bit If the write port of the ISIF module overflows when writing data to SDRAM, this bit will toggle. 0x0: No overflow pending (r) No action (w) 0x1: Overflow pending (r) Clear overflow (w)	RW	0
10:8	CCDW	This bit enables to shift right (divide) the up-to-12-bit RAW data value when writing out to SDRAM. The effect is that the dynamic of the output signal is decreased. The ISIF_MODESET.CCDW, ISIF_HSIZE.ADCR, ISIF_HSIZE.HSIZE, ISIF_CCDCFG.BSWD, ISIF_CCDCFG.MSBINV, ISIF_CCDCFG.SDRPACK bit fields control how pixel data are stored to SDRAM. 0x6: Reserved 0x1: 1-bit right shift out[15:0] = 00000 & data[11:1] 0x7: Reserved 0x0: No shift out[15:0] = 0000 & data[11:0] 0x2: 2-bit right shift out[15:0] = 000000 & data[11:2] 0x4: 4-bit right shift out[15:0] = 00000000 & data[11:4] 0x5: Reserved 0x3: 3-bit right shift out[15:0] = 0000000 & data[11:3]	RW	0x0
7	CCDMD	Field mode: This bit selects the type of image sensor: interlaced or progressive 0x0: Progressive image sensor 0x1: Interlaced image sensor	RW	0
6	DPOL	Image sensor input data polarity 0x0: No change 0x1: One's complement	RW	0
5	SWEN	External WEN selection In case this bit and SYNCEN.DWEN are set to 1, the external WEN signal is used to store image sensor data to memory. 0x0: WEN not used 0x1: Use external WEN	RW	0

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
4	FIPOL	FLD Signal Polarity 0x0: Positive 0x1: Negative	RW	0
3	HDPOL	HD Sync Signal Polarity 0x0: Positive 0x1: Negative	RW	0
2	VDPOL	VD Sync Signal Polarity 0x0: Positive 0x1: Negative	RW	0
1	FIDD	FLD Signal Direction. There must be at least three clock cycles between the time this bit is modified and the HD/VD pulse for the start of frame comes. 0x0: Input 0x1: Output	RW	0
0	HDVDD	VD,HD Sync Signal Direction. There must be at least three clock cycles between the time this bit is modified and the HD/VD pulse for the start of frame comes. 0x0: Input 0x1: Output	RW	0

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15	VLDC	On/off control of CPU registers resynchronize function by VSYNC. All the others are shadowed registers, where register values are updated at V-sync timing by default. If VDLC=1, ISIF register values are updated immediately after register write just like non-shadowed registers. 0x0: Enable 0x1: Disable	RW	0
14	RESERVED	Reserved. must always be set to 0.	RW	0
13	MSBINVI	MSB inverse of CIN port when the data are captured to SDRAM. The ISIF_MODESET.CCDW, ISIF_HSIZE.ADCR, ISIF_HSIZE.HSIZE, ISIF_CCDCFG.BSWD, ISIF_CCDCFG.MSBINV, ISIF_CCDCFG.SDRPACK bit fields control how pixel data are stored to SDRAM. 0x0: Disable 0x1: Enable	RW	0
12	BSWD	On/off control of Byte SWAP function when SDRAM capturing. The ISIF_MODESET.CCDW, ISIF_HSIZE.ADCR, ISIF_HSIZE.HSIZE, ISIF_CCDCFG.BSWD, ISIF_CCDCFG.MSBINV, ISIF_CCDCFG.SDRPACK bit fields control how pixel data are stored to SDRAM. 0x0: Disable 0x1: Enable (swap)	RW	0
11	Y8POS	Selects Y signal position when in 8bit input mode 0x0: even pixel 0x1: odd pixel	RW	0
10	EXTRG	Setting 1 to this register, the SDRAM address is initialized at the rising edge of FID input signal or DWEN register.	RW	0
9	TRGSEL	Select trigger source signal of SDRAM address initializing in case EXTRG=1. 0x0: DWEN register 0x1: FID input port	RW	0
8	WENLOG	Specifies the CCD valid area. 0x0: internal valid signal and WEN signal is ANDed logically. 0x1: internal valid signal and WEN signal is ORed logically.	RW	0
7:6	FIDMD	Specifies FID detection mode 0x0: latch the FID at the VSYNC timing 0x1: no latch the FID 0x3: Reserved 0x2: Reserved	RW	0x0
5	BT656	Selects bit width of CCIR656. This bit applies only if ISIF_REC656IF.R656ON = 1. 0x0: 8 bits 0x1: 10 bits	RW	0

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
4	YCINSWP	The ISIF module has a 16-bit interface. When 16-bit YUV data are input, the luma data (YIN7-0) are expected to be on the 8 MS bits and the chroma (CIN7-0) data are expected to be on the LS bits. This bit enables to swap the 8 MS bits with the 8 LS bits of the interface in case the luma and chroma do not come in the correct order. See Section 8.3.3.6.2, *ISS ISP ISIF Top-Level Block Diagram*. 0x0: YIN7-0 = Y signal / CIN7-0 = C signal 0x1: YIN7-0 = C signal / CIN7-0 = Y signal	RW	0
3	RESERVED	Reserved. must always be set to 0.	RW	0
2	RESERVED	Reserved. must always be set to 0.	RW	0
1:0	SDRPACK	This bit field selects how the data are stored to SDRAM. There can be 8, 12 or 16 bits per pixel. The ISIF_MODESET.CCDW, ISIF_HSIZE.ADCR, ISIF_HSIZE.HSIZE, ISIF_CCDCFG.BSWD, ISIF_CCDCFG.MSBINV, ISIF_CCDCFG.SDRPACK bit fields control how pixel data are stored to SDRAM. 0x0: 16 bits / pixel 0x1: 12 bits / pixel 0x3: Reserved 0x2: 8 bits / pixel	RW	0x0

RESERVED																														SYNCOFF	ENABLE

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
31:2	RESERVED		R	0x0000 0000
1	SYNCOFF	VD output mask This register masks the VD output to the IPIPE module. This can be useful when one wants to read data from SDRAM which are stored in a double buffer. If the VD is not masked each time we start the module an new VD will be generated to the IPIPEIF module. Let's consider two buffers A and B of N lines each. *This bit field is latched by VD. 0x0: VD output mask is disabled. 0x1: VD output mask is enabled.	RW	0
0	ENABLE	IPIPE I/F Enable This register is used to start the operation of SDRAM buffer memory read and generates SYNC signals. This register is available when INPSRC1 or INPSCR2 = 1, 2 or 3. 0x0: disable 0x1: enable	RW	0

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:14	INPSRC1	Selects the source for the mux (VPORT / ISIF / SDRAM) as well as the data format type. 0x0: VPORT_RAW 0x1: SDRAM_RAW 0x3: SDRAM_YUV 0x2: ISIF_DARKFM Input ports to DFS submodule are VPORT and SDRAM.	RW	0x0

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
13:11	DATASFT	SDRAM read data shift This register is available when INPSRC1 or INPSRC2 = 1 or 2, that is, when data are read from SDRAM. 0x6: Output data[11:0] = (read data[15:4] >> 4) & 0x0FFF 0x1: Output data[11:0] = (read data[11:0] << 1) & 0x0FFF 0x7: Output data[11:0] = (read data[15:4] >>4) & 0x0FFF 0x0: Output data[11:0] = (read data[11:0]) & 0x0FFF 0x2: Output data[11:0] = (read data[11:0] << 2) & 0x0FFF 0x4: Output data[11:0] = (read data[11:0] << 4) & 0x0FFF 0x5: Output data[11:0] = (read data[15:4] >> 4) & 0x0FFF 0x3: Output data[11:0] = (read data[11:0] << 3) & 0x0FFF	RW	0x0
10	CLKSEL	IPIPEIF and IPIPE module pixel clock selection. This register must be set to 1 when INPSRC1 or INPSRC2 = 1 or 3, that is, data are solely read from SDRAM (VPORT inactive). 0x0: Selects the pixel clock from the VPORT. 0x1: Selects the pixel clock from the fractional clock divider. The fractional clock divider value is setup with the IPIPEIF_CLKDIV register.	RW	0
9:8	UNPACK	8-Bit, 12-bit Packed Mode When sensor raw data are stored in 8-bit packed mode or 12-bit packed mode, this register should code 1 or 3. This register is effective when INPSRC = 1 or 2. 0x0: 16 bits / pixel 0x1: 8 bits / pixel 0x3: 12 bits / pixel 0x2: 8 bits / pixel + inverse A law (8 bits to 10 bits)	RW	0x0
7	AVGFILT	Averaging Filter It applies (1,2,1) filter for the RGB/YCbCr data. *This bit field is latched by VD. 0x0: disable 0x1: enable	RW	0
6:4	RESERVED		R	0x0
3:2	INPSRC2	Selects the source for the mux (ISIF / SDRAM) as well as the data format type. 0x0: ISIF 0x1: SDRAM_RAW 0x3: SDRAM_YUV 0x2: ISIF_DARKFM Input ports to DFS submodule are ISIF and SDRAM.	RW	0x0
1	DECIM	Pixel Decimation The decimation rate defined by RSZ register. *This bit field is latched by VD. 0x0: No decimation 0x1: Decimation	RW	0
0	ONESHOT	One Shot Mode This register is available when INPSRC = 1 or 3. 0x0: Continuous mode 0x1: One shot mode	RW	0

Bits	Field Name	Description	Type	Reset
31:8	RESERVED		R	0x000000
7	YUV8P	8-bit YUV data unpacking to 16 bits When IPIPEIF_CFG1.INPSRC2 = 0 and IPIPEIF_CFG2.YUV16 = 1, the 8-bit YUV data are transformed into 16-bit YUV data. The way the data are unpacked from 8 bits to 16 bits is controlled by the IPIPEIF_CFG2.YUV8P register. The upper 8 bits of the 16-bit output are set to 0. 0x0: Y output on even pixels C output on odd pixels 0x1: C output on even pixels Y output on odd pixels	RW	0
6	YUV8	YUV 8bit mode When ISIF_CFG1.INPSRC2 = 0 and YUV16 = 1, setting this bit to 1 enables the conversion from 8-bit YUV input to 16-bit YUV. This register is used when the input data from the ISIF module is 8-bit YUV data. 0x0: YUV16 0x1: YUV8 to 16	RW	0
5	DFSDIR	DFS direction Selects the direction of dark frame subtraction. 0x0: VPORT IF(capture frame) - SDRAM (dark frame) 0x1: SDRAM (capture frame) - VPORT IF(dark frame)	RW	0
4	RESERVED	Read returns reset value	RW	0

3	YUV16	Data type selection. The behavior of this bit field depends upon other register settings. The functionality is best explained with the following pseudo code:
		if ((CFG1.INPSRC2==0 && CFG2.YUV16) ||
		CFG1.INPSRC2==3) {
		data_out[15:0] = yuv[15:0]
		}
		else if (CFG1.INPSRC2==1 && CFG2.YUV16 &&
		CFG1.UNPACK=1) {
		data_out[15:8] = gain_clip[7:0];
		data_out[7:0] = 0;
		}
		else {
		data_out[15:12] = 0;
		data_out[11: 0] = gain_clip[11:0];
		}
		where:
		o data_out[15:0] = 16-bit YUV or 12-bit RAW data to ipipe
		o yuv[15:0] = 16-bit YUV data from "horizontal pixel decimator" block.
		o gain_clip[11:0] = 12-bit RAW data from "gain" block.
		0x0: 12-bit RAW data
		0x1: 16-bit YUV data
			RW	0

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:6	RESERVED		R	0x0000
5:2	FIFOWMRKLVL	To guarantee that the FIFO does not overflow, the stall request is deasserted only when a certain number of locations in the FIFO are free. The number of free locations is configurable. A safe number of mandatory free locations can be configured by taking into consideration the pixel clock frequency (PCLK) with respect to that of the functional clock (ISP_FCLK). The worst case occurs when PCLK = ISP_FCLK. In that case, value should be configured to 0 (i.e. 16 free locations), so that the stall will be deasserted only when the 16-deep FIFO is completely empty. 0: Stall deassertion when FIFO is empty (16 free locations) and SDRAM data available; 1: Stall deassertion when FIFO has not more than 1 valid entry and SDRAM data available; … 15: Stall deassertion when FIFO has not more than 15 valid entries and SDRAM data available;	RW	0x0
1	ENM2MSTAL	Enable memory-to-memory stall mechanism: 0: disable (no special stall mechanism for memory-to-memory use cases); 1: enable (stall mechanism for memory-to-memory use cases);	RW	0
0	DTUDF	Data under flow error status register. Reading 1 shows there is data under flow and at least one data is corrupted while reading from SDRAM. Writing 1 to this register clears (=0) the error (=1) status. Underflow errors are non recoverable at ISP level, need to do a soft reset at ISS level. The IPIPEIF_UDF interrupt is generated when an underflow happens. The interrupt avoids polling this register for errors. If bit [1] ENM2MSTAL = 1, then programmers need to ensure that the SW does not clear bit [0] DTUDF, as this would reset the MTC read interface. Bit DTUDF can be cleared only in the on-the-fly operation where the stall mechanism will not work.	RW	0

Bits	Field Name	Description	Type	Reset
31:22	AVE2LMT	AE/AWB Saturation Limit This is the value that all sub sampled pixels in the AE/AWB engine are compared to. If the data is greater or equal to this data then the block is considered saturated.	RW	0x3FF
21	OVF	H3A module overflow status bit. If the H3A module overflows it will keep sending data. The software can read this status bit during vertical blanking period to ensure that no overflow happened while writing out the data to SDRAM. There is also an interrupt at ISP level (H3A_OVF) which can be used to monitor this. 0x0: Read 0: No overflow pending Write 0: Status bit unchanged 0x1: Read 1: Overflow happened while writing out the data. Output data likely to be corrupted. Write 1: Clear the status bit.	RW	0
20	AF_VF_EN	AF Vertical Focus Enable 0x0: 4 Color Horizontal FV only 0x1: 1 Color Horizontal FV and 1 Color Vertical FV	RW	0
19	AEW_MED_EN	AE/AWB Median filter Enable If the median filter is enabled, then the 1st 2 and last 2 pixels in the frame are not filtered. 0x0: Disable Auto Focus median filter 0x1: Enable Auto Focus median filter	RW	0
18	BUSYAEAWB	Busy bit for AE/AWB	R	0
17	AEW_ALAW_EN	AE/AWB A-law Enable 0x0: Disable Auto exposure/white balance A-law table 0x1: Enable Auto exposure/white balance A-law table.	RW	0
16	AEW_EN	AE/AWB enable 0x0: Disable Auto exposure/white balance 0x1: Enable Auto exposure/white balance	RW	0
15	BUSYAF	Busy bit for AF.	R	0

PRELIMINARY

RESERVED								AFINCH								AFINCV								PAXVC							
PAXHC																															

Bits	Field Name	Description	Type	Reset
31:21	RESERVED		R	0x000
20:17	AFINCH	AF Engine Column Increments Number of columns to increment in a paxel plus 1 multiplied by 2. Thus, the number of columns that can be skipped between two processed line pairs is 2-32 (even). The starting two columns in a paxel are first processed before this field is applied. This must be set so that there are at least 4 samples on a line when combined with the number of horizontal paxels. * This value is shadowed and latched on the rising edge of VSYNC.	RW	0x0
16:13	AFINCV	AF Engine Line Increments Number of lines to increment in a Paxel plus 1 multiplied by 2. Incrementing the line in a paxel is always done on a line pair due to the fact that the RGB pattern falls in two lines. If all the lines are to be processed, this field should be set to zero, and thus line count is incremented by 2 following a line pair. Thus, the number of lines that can be skipped between two processed line pairs is 0-30 (even). The starting two lines in a paxel are first processed before this field is applied. * This value is shadowed and latched on the rising edge of VSYNC.	RW	0x0

PRELIMINARY

Bits	Field Name	Description	Type	Reset
12:6	PAXVC	AF Engine Vertical Paxel Count The number of paxels in the vertical direction plus 1. The maximum number of vertical paxels in a frame should not exceed 128. The value should be set to ensure that the bandwidth requirements and buffer size are not exceeded. * This value is shadowed and latched on the rising edge of VSYNC.	RW	0x00
5:0	PAXHC	AF Engine Horizontal Paxel Count The number of paxels in the horizontal direction plus 1. It is illegal to set a number that is greater than 35 (total of 36 paxels in the horizontal direction). The minimum number of paxels should be 2 (valid range for the field is 1-35). * This value is shadowed and latched on the rising edge of VSYNC.	RW	0x00

Bits	Field Name	Description	Type	Reset
31:24	WINH	AE/AWB Engine Window Height This specifies the window height in an even number of pixels, the window height is the value plus 1 multiplied by 2. The final value can be from 2-512 (even) * This value is shadowed and latched on the rising edge of VSYNC.	RW	0x00
23:21	RESERVED		R	0x0
20:13	WINW	AE/AWB Engine Window Width This specifies the window width in an even number of pixels, the window width is the value plus 1 multiplied by 2. The minimum width is 16 pixels, if the pixel clock is half or less of the ISP_FCLK clock. If the pixel clock is equal to ISP_FCLK, then the minimum width is 32 pixels. * This value is shadowed and latched on the rising edge of VSYNC.	RW	0x00
12:6	WINVC	AE/AWB Engine Vertical Window Count The number of windows in the vertical direction plus 1. The maximum number of vertical windows in a frame should not exceed 128. The value should be set to ensure that the bandwidth requirements and buffer size are not exceeded * This value is shadowed and latched on the rising edge of VSYNC.	RW	0x00
5:0	WINHC	AE/AWB Engine Horizontal Window Count The number of horizontal windows plus 1. The maximum number of horizontal windows is 35 plus 1 (36). The minimum number of windows should be 2 (valid range for the field is 1-35). * This value is shadowed and latched on the rising edge of VSYNC.	RW	0x00

8.4 ISS Still Image Coprocessor

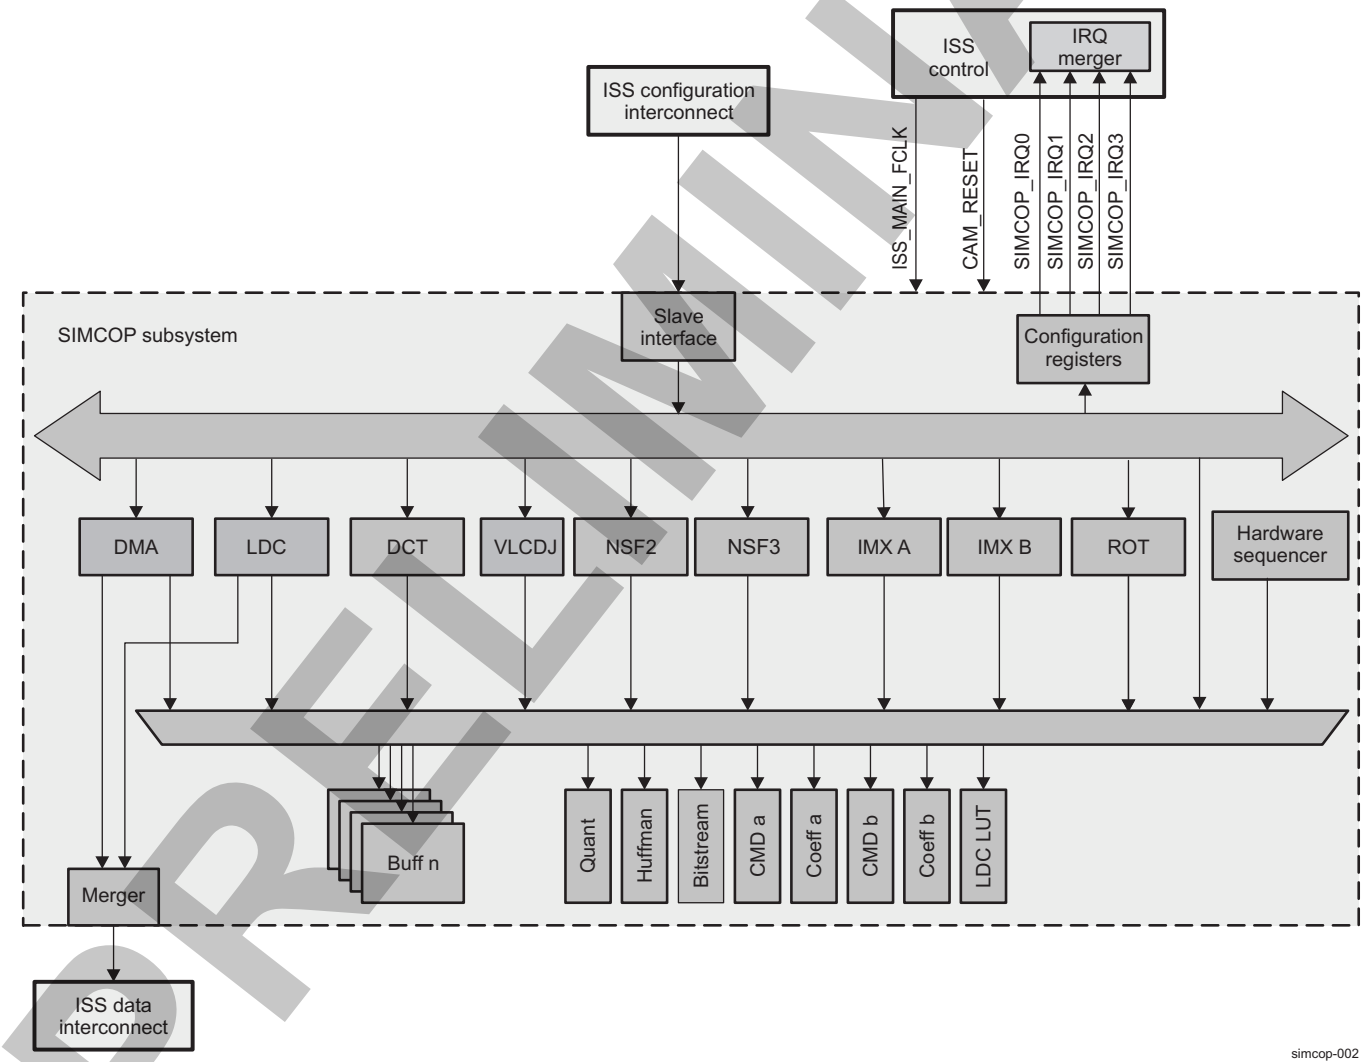
This section gives a high-level description of the ISS still iMage coprocessor (SIMCOP) in the device. For a high-level description of ISS level, see Section 8.1, *ISS:Overview*.

8.4.1 ISS SIMCOP Overview

The SIMCOP subsystem is designed to encode, decode, and process image data. SIMCOP is a macroblock-based memory-to-memory processing engine. It fetches macroblocks from system memory and stores them into local memories. Different accelerators take the fetched data, perform processing, and send the processing outcome back to local memories. From there the data could be further processed by other accelerators or sent back to system memory. The SIMCOP needs an external central processing unit (CPU) to perform high-level control tasks and configurations. SIMCOP is closely coupled to a CPU for that purpose.

Figure 8-256 shows a block diagram of the SIMCOP subsystem.

Figure 8-256. SIMCOP Subsystem Overview



The ISS SIMCOP subsystem consists of:

- Noise filter (NSF2 and NSF3) – For advanced noise filtering and an edge-enhancement
- Two image and video processing engines (IMXs) – Supplement various fixed-function processing blocks
- Variable-length coder/decoder for JPEG (VLCDJ) module – Handles quantization and variable length

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

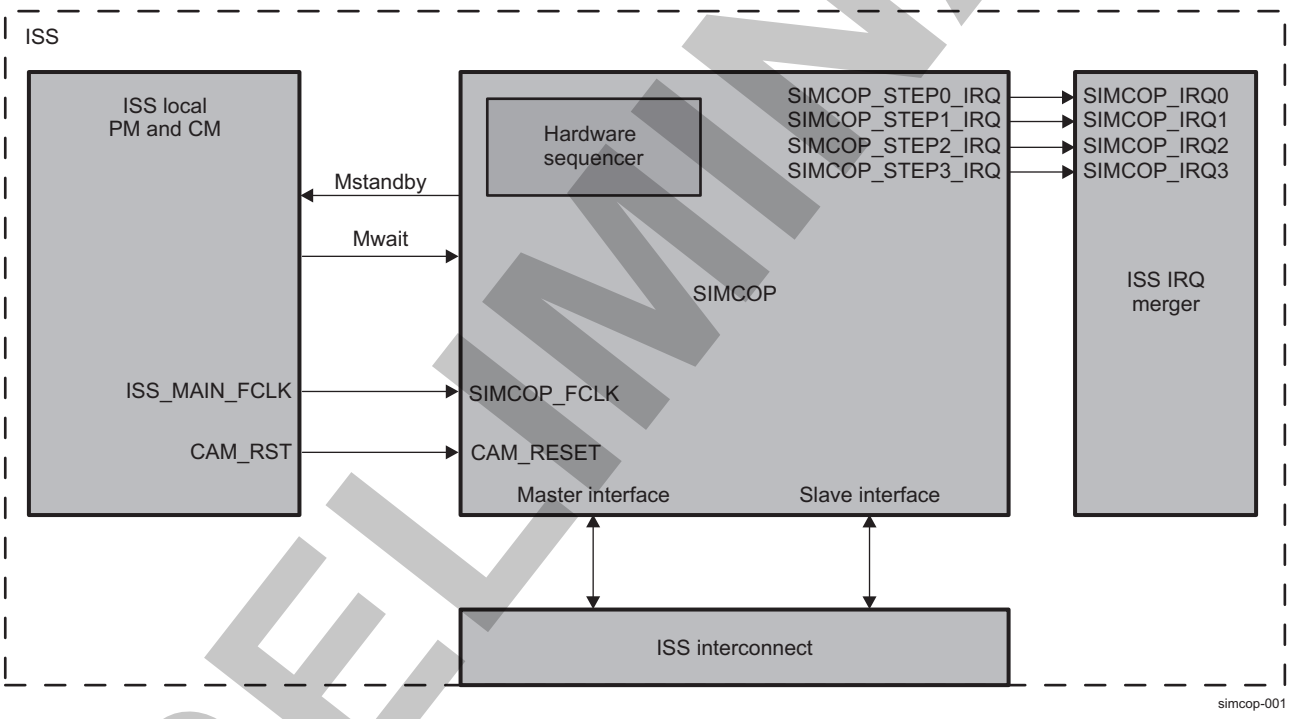
coding, decoding, and inverse quantization

- Discrete cosine transform (DCT) module – Implements method for transforming blocks of image during the compression flow.
- Lens distortion correction (LDC) module – Deals with lens geometric distortion issues in the camera subsystem
- Rotation accelerator (ROT) engine – Blocks data rotation and shifting from a SIMCOP local memory to another SIMCOP local memory
- Hardware sequencer and buffers – Controls SIMCOP modules and buffers to offload an external processor to perform low-level sequencing tasks
- Direct memory access (DMA) controller – Data transfers from SIMCOP memories to system memory or from system memory to SIMCOP memories

8.4.1.1 ISS SIMCOP Integration

The SIMCOP subsystem is connected to the rest of the system through the ISS local interconnect. Figure 8-257 shows the integration of the SIMCOP subsystem in the ISS.

Figure 8-257. SIMCOP Integration



NOTE: For more information about the IDLE hardware handshake and the wake-up request, see Section 3.1.1.1, *Clock Management* in Section 3.1.1 , *Power, Reset, and Clock Management*.

This section gives an overview of typical uses of the module. See Section 3.1.1, *Power, Reset, and Clock Management* for more information and settings of the PRCM relationship to ISS clocks and resets.

Table 8-1344 lists the Integration Attributes.

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
SIMCOP	SIMCOP_STEP0_IRQ	SIMCOP_IRQ0	SIMCOP IRQ merger	Event triggered when a SIMCOP context is activated by the hardware sequencer
SIMCOP	SIMCOP_STEP1_IRQ	SIMCOP_IRQ1	SIMCOP IRQ merger	Event triggered when a SIMCOP context is activated by the hardware sequencer
SIMCOP	SIMCOP_STEP2_IRQ	SIMCOP_IRQ2	SIMCOP IRQ merger	Event triggered when a SIMCOP context is activated by the hardware sequencer
SIMCOP	SIMCOP_STEP3_IRQ	SIMCOP_IRQ3	SIMCOP IRQ merger	Event triggered when a SIMCOP context is activated by the hardware sequencer

For more information about interrupt requests, see Section 8.1.2.1.1*Interrupt Merger*.

8.4.1.2 ISS SIMCOP Functional Description

8.4.1.2.1 ISS SIMCOP Local Power and Clock Management

8.4.1.2.1.1 ISS SIMCOP Local Clock Management

The ISS has five asynchronous clock domains. The SIMCOP belongs to the ISS_PCLK clock domain.

A clock-enable signal provided externally is used. Multiple subdomains exist internally to reduce dynamic power consumption. This feature does not require intervention by the PRCM module. For high-level description of the SIMCOP clock domain and configuration inside ISS, see Section 8.1.1.1.1, *ISS Clock Domains* and , *ISS Clocks*.

Moreover, at high level the functional clock of ISS SIMCOP submodules can be cut by software to reduce power consumption by cutting off or turning on the modules from the SIMCOP_CLKCTRL register (see Table 8-1347).

For software to enable a submodule:

- Software sets the appropriate bit in the SIMCOP_CLKCTRL register.
- Hardware enables the submodule functional and interface clocks.
- Hardware connects the configuration port of the submodule to the coprocessor bus.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- Hardware sets the appropriate bit in the SIMCOP_CLKCTRL register. Software must check if this bit is set before accessing the submodule.

Table 8-1347 shows the ISS SIMCOP clock control register settings.

Table 8-1347. ISS SIMCOP Clock Control Register Settings

Module Name	Bit Field Name	Description
NSF3	SIMCOP_CLKCTRL[9] NSF3	Writing 0x1 enables the module
ROT	SIMCOP_CLKCTRL[7] ROT_A	Writing 0x1 enables the module
IMX_B	SIMCOP_CLKCTRL[6] IMX_B	Writing 0x1 enables the module
IMX_A	SIMCOP_CLKCTRL[5] IMX_A	Writing 0x1 enables the module
NSF2	SIMCOP_CLKCTRL[4] NSF2	Writing 0x1 enables the module
VLCDJ	SIMCOP_CLKCTRL[3] VLCDJ	Writing 0x1 enables the module
DCT	SIMCOP_CLKCTRL[2] DCT	Writing 0x1 enables the module
LDC	SIMCOP_CLKCTRL[1] LDC	Writing 0x1 enables the module
DMA	SIMCOP_CLKCTRL[0] DMA	Writing 0x1 enables the module

For software to shut down a submodule:

- Software ensures that the submodule is idle. Mainly:
  - The submodule must not generate new events.
  - The submodule must not have any pending events.
  - For initiators, the submodule must stop interconnect transaction generation.
- Software clears the appropriate bit in the SIMCOP_CLKCTRL register.
- Hardware disconnects the configuration port of the module from the coprocessor bus, no more accesses are routed to the submodule. Ongoing transactions are finished (hardware stays in this state as long as required).
- For initiators, hardware waits until there are no more outstanding transactions:
  - The SIMCOP DMA provides an MStandBy signal used for that purpose.
  - The LDC does not provide this information. Software must ensure that LDC is idle. SIMCOP hardware ensures that the internal MTC2OCP bridges have no outstanding transactions.
- Hardware cuts the submodules clock.
- Hardware clears the appropriate SIMCOP_CLKCTRL registers.

SIMCOP submodules support autogating. They can gate their functional and interface clock internally based on functional requirements. This feature can be disabled for debug or power consumption measurement purposes.

8.4.1.2.1.2 Local Clock Autogating

The SIMCOP subsystem modules support autogating. They can gate their functional and interface clock internally based on functional requirements. This feature can be disabled. Table 8-1348 summarizes what modules support autogating control and which control bit is used.

Table 8-1348. Autoclock Gating Bit Control

SIMCOP resource	Autogating override
SIMCOP top-level resources	NA
SIMCOP DMA	NA
LDC	NA
DCT	DCT_CFG[5] AUTOGATING
VLCDJ	VLCDJ_CTRL[3] AUTOGATING
NSF2	NA
NSF3	NA

Table 8-1348. Autoclock Gating Bit Control (continued)

SIMCOP resource	Autogating override
IMX A	IMXa.IMX_CLKCNTRL[0] CLKCNTRL
IMX B	IMXb.IMX_CLKCNTRL[0] CLKCNTRL
ROT	ROT_CFG[9] AUTOGATING

8.4.1.2.1.3 ISS SIMCOP Power Management

The SIMCOP supports the STANDBY power management protocol. It is used by the SIMCOP to indicate when it has no more interconnect transactions to perform. This information is used at the ISS level to control the SIMCOP and ISS shut-down sequence. The SIMCOP does not have any internal wake-up events. DISCONNECT and IDLE protocols are not supported.

The typical SIMCOP shut-down sequence is:

- Software disables all SIMCOP submodules. This ensures the SIMCOP does not:
  - Generate any traffic on its master port; SIMCOP asserts the MStandby signal.
  - Generate new events (IRQs).
- Software clears all pending events at the SIMCOP level; all interrupt lines become inactive.
- Software initiates the SIMCOP shut-down sequence by writing the appropriate bit at the ISS level.
- ISS hardware:
  - Disconnects the SIMCOP configuration port. Any access attempts to the SIMCOP are blocked at the ISS level. The DISCONNECT protocol is handled at the ISS level; the SIMCOP does not provide any handshake signals to support it.
  - Waits until MStandby from SIMCOP is asserted (always true in a normal case because SIMCOP submodules are inactive)
  - Asserts the SWait input of SIMCOP
  - Cuts the SIMCOP clock

The typical SIMCOP enable sequence is:

- Software initiates the SIMCOP enable sequence by writing the appropriate bit at the ISS level.
- ISS hardware:
  - Enables the SIMCOP clock
  - Deasserts the SWait input of SIMCOP
  - Connects the SIMCOP configuration port

Three modes for MStandBy control are supported. The mode is selected using the SIMCOP_HL_SYSCONFIG[5:4] STANDBYMODE register.

- Smart-standby: This is the normal mode to be used. When in this mode, SIMCOP asserts the MStandBy signal when the MStandBy output of SIMCOP DMA is asserted, the LDC module is effectively disabled (SIMCOP_CLKCTRL[1] LDC = 0), and the MTCR2OCP bridge and the merger have no more outstanding transactions.
- Force-standby: This is a backup mode intended to be used only if smart-idle mode is bugged. When in this mode, SIMCOP asserts MStandBy unconditionally. Software must ensure that the SIMCOP is in a correct quiet state before programming this mode.
- No-standby: This is a backup mode intended to be used only if smart-idle mode is bugged. When in this mode, SIMCOP never asserts the MStandBy signal.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

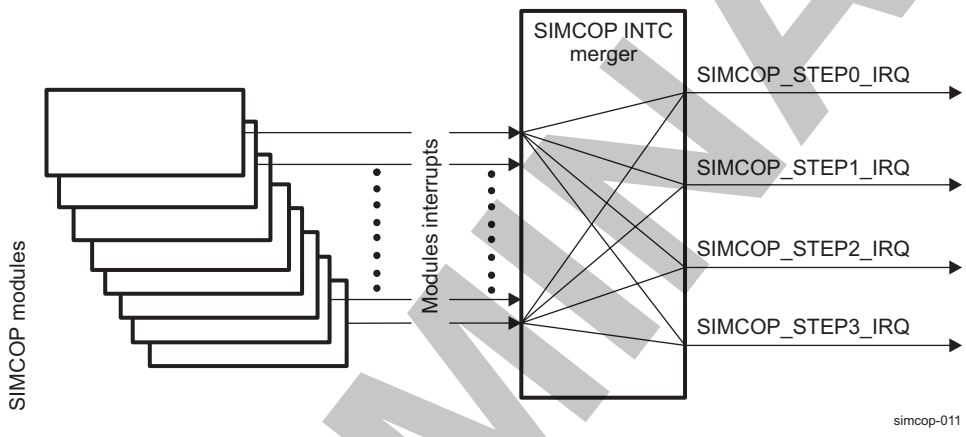
8.4.1.2.2 Software Reset

Software reset is intended to return the SIMCOP into a known state without requiring a complete device reset. A software reset at the SIMCOP level is seen as a hardware reset for SIMCOP submodules. To perform a software reset, set the SIMCOP_HL_SYSCONFIG[0] SOFTRESET bit to 1. The SIMCOP_HL_SYSCONFIG[0] SOFTRESET bit indicates that the software reset is ongoing when its value is 1. When the software reset completes, the SIMCOP_HL_SYSCONFIG[1] SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before configuring hardware sequencer or buffers.

8.4.1.2.3 Interrupt Merger

SIMCOP interrupts are merged at the SIMCOP subsystem level into four interrupts as shown in Figure 8-258.

Figure 8-258. SIMCOP Interrupt Merger Overview



These four outputs interrupts can be configured using the SIMCOP_HL_IRQENABLE_SET_i and SIMCOP_HL_IRQENABLE_CLR_i (i = 0 to 3, corresponding to output interrupt) to enable or disable interrupt mask for each interrupt output. Software can poll the value of interrupt before masking SIMCOP_HL_IRQSTATUS_RAW_i and after masking SIMCOP_HL_IRQSTATUS_i.

Software can configure how outputs interrupts are generated by using the SIMCOP_CTRL[i] IRQi_MODE (i = 0 to 3) bit field(s):

- 0x0: OR – The interrupt is asserted when one of the selected events has occurred
- 0x1: AND – The interrupt is asserted when all selected events have occurred

Table 8-1349 shows how interrupts are mapped on the SIMCOP_HL_IRQSTATUS_RAW_i, SIMCOP_HL_IRQSTATUS_i, SIMCOP_HL_IRQENABLE_SET_i and SIMCOP_HL_IRQENABLE_CLR_i registers.

Table 8-1349. SIMCOP Interrupts

Bit	Name	Description
0	SIMCOP_DMA_IRQ0	Interrupt triggered by SIMCOP DMA
1	LDC_FRAME_IRQ	A full frame has been processed by LDC2 module
2	DCT_IRQ	DCT operation has been completed (configured number of MCUs for YUV4:2:0/YUV4:2:2 mode, or number of blocks for sequential block mode)
3	VLCDJ_BLOCK_IRQ	A macroblock has been processed (encode/decode)
4	NSF_IRQ	Event triggered by the NSF2 imaging accelerator when processing of a block is done.
5	IMX_A_IRQ	Event triggered when IMX has executed a SLEEP instruction.
6	IMX_B_IRQ	
7	ROT_A_IRQ	Event triggered by the ROT engine.
8	NSF3_IRQ	Event triggered by the NSF3 imaging accelerator when processing of a block is done.
9	LDC_BLOCK_IRQ	A macroblock has been processed by LDC2 module

Copyright © 2013, Texas Instruments Incorporated
PRELIMINARY

Table 8-1349. SIMCOP Interrupts (continued)

Bit	Name	Description
10	SIMCOP_STEP0_IRQ	Event triggered when a SIMCOP context is activated by the HW sequencer
11	SIMCOP_STEP1_IRQ	
12	SIMCOP_STEP2_IRQ	
13	SIMCOP_STEP3_IRQ	
14	DONE_IRQ	Event triggered when the HW sequencer finishes the sequence: - the sequence step counter has reached the limit - All accelerator and DMA events for the last sequence step have been received.
15	VLCDJ_DECODE_ERR_IRQ	A decode error has been signaled by the VLCDJ module
16	ICNT_ERR_IRQ	An error has been received on the SIMCOP master port on L3 interconnect.
17	LDC2BRIDGE_ERR_IRQ	The LDC2 bridge has generated an error. This event shall not trigger in a normal use case.
18	SIMCOP_DMA_IRQ1	Interrupt triggered by SIMCOP DMA
19	CPU_PROC_START_IRQ	This interrupt is used when CPU data processing is used in a macroblock processing pipeline. When CPU receives this IRQ, data for ready to be processed. When CPU is done with processing it acknowledges by setting the SIMCOP_HWSEQ_CTRL.CPU_PROC_DONE bit. The interrupt is cleared as usual.

8.4.1.2.4 ISS SIMCOP Modules Description

This section provides links to each subchapter for each submodule in the ISS SIMCOP module.

The ISS module provides a unique ISS_MAIN_FCLK for all the submodules inside the SIMCOP, see Section 8.4.1.2.1.1.

For information about hardware and software resets for each module, see Table 8-1349.

For interrupt request information for each module, see Table 8-1346.

The ISS SIMCOP consists of the following submodules:

- Hardware Sequencer and buffers, for more information, see Section 8.4.2.
- DMA, for more information, see Section 8.4.3.
- ROT, for more information, see Section 8.4.7.
- IMX, for detailed information about the IMX modules, contact your TI representative.
- NSF2, for detailed information about the NSF2 modules, contact your TI representative.
- NSF3, for detailed information about the NSF3 modules, contact your TI representative.
- VLCDJ, for more information please see Section 8.4.6
- DCT, for more information, see Section 8.4.5
- LDC, for more information, see Section 8.4.4

8.4.1.3 ISS SIMCOP Programming Models

8.4.1.3.1 Global Initialization

8.4.1.3.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the ISS SIMCOP module is to be used for the first time after a device reset. This initialization of the surrounding modules is based on the integration of the ISS SIMCOP.

Table 8-1350. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
ISS local PM and CM	Module interface and functional clocks must be enabled. For more information, see Section 8.4.1.2.1, *ISS SIMCOP Local Power and Clock Management*.

PRELIMINARY

8.4.1.3.1.2 ISS SIMCOP Module Global Initialization

This procedure initializes the ISS SIMCOP module after a power-on or software reset.

Table 8-1351. ISS SIMCOP Global Initialization

Step	Register/ Bitfield / Programming Model	Value
Execute software reset	SIMCOP_HL_SYSCONFIG[0] SOFTRESET	0x1
Wait until reset completed?	SIMCOP_HL_SYSCONFIG[0] SOFTRESET	0x0
Configure standby mode	SIMCOP_HL_SYSCONFIG[5:4] STANDBYMODE	0x2
Configure submodules interface and functional clock	SIMCOP_CLKCTRL[7:0]	xxx
Interrupt configuration		
Set interrupt enable bit for the submodules	SIMCOP_HL_IRQENABLE_SET_i[7:0]	xxx

8.4.1.3.2 ISS SIMCOP Operational Modes Configuration

8.4.1.3.2.1 Interrupts

To unmask an interrupt for generation of the SIMCOP_IRQi output interrupts, software must set the corresponding bit of the SIMCOP_HL_IRQENABLE_SET_i (i = 0 to 3) register to 1.

Example 1:

SIMCOP_IRQ1 is generated when DCT_IRQ or VLCDJ_BLOCK_IRQ are generated:

- SIMCOP_HL_IRQENABLE_SET_i[2] DCT_IRQ = 0x1 (i = 1)
- SIMCOP_HL_IRQENABLE_SET_i[3] VLCDJ_BLOCK_IRQ = 0x1 (i = 1)
- SIMCOP_CTRL[1] IRQ1_MODE = 0x0

Example 2:

SIMCOP_IRQ3 is generated when IMX_A_IRQ and LDC_BLOCK_IRQ are generated:

- SIMCOP_HL_IRQENABLE_SET_i[5] IMX_A_IRQ = 0x1 (i = 3)
- SIMCOP_HL_IRQENABLE_SET_i[9] LDC_BLOCK_IRQ = 0x1 (i = 3)
- SIMCOP_CTRL[3] IRQ3_MODE = 0x1

To mask an interrupt for generation of the SIMCOP_IRQi output interrupts, software must clear the corresponding bit of the SIMCOP_HL_IRQENABLE_CLEAR_i (i = 0 to 3) register by setting it to 0.

When an event occurs, the corresponding bit in the SIMCOP_HL_IRQSTATUS_RAW_i (i = 0 to 3) register is set regardless of whether or not the event has been enabled. Bits in the SIMCOP_HL_IRQSTATUS_i (i = 0 to 3) registers are only set when an enabled event occurs. Software can clear a pending event by setting the appropriate bit in the SIMCOP_HL_IRQSTATUS_i (i = 0 to 3) register.

8.4.1.3.2.2 JPEG Encode Operational Mode Configuration

Bits	Field Name	Description	Type	Reset
31:6	RESERVED	Read returns 0.	R	0x0000000
5:4	STANDBYMODE	Configuration of the local initiator state management mode. By definition, initiator may generate read/write transaction as long as it is out of STANDBY state. 0x0: Force-standby mode: local initiator is unconditionally placed in standby state. Backup mode, for debug only. 0x1: No-standby mode: local initiator is unconditionally placed out of standby state. Backup mode, for debug only. 0x2: Smart-standby mode: local initiator standby status depends on local conditions, i.e. the module's functional requirement from the initiator.	RW	0x0
3:1	RESERVED	Read returns 0.	R	0x0
0	SOFTRESET	Software reset Read 0x0: Reset done, no pending action Write 0x0: No action Write 0x1: Initiate software reset Read 0x1: Reset (software or other) ongoing	RW	0

PRELIMINARY

Bits	Field Name	Description	Type	Reset
31:30	NSF3_WMEM	Selects working memory for NSF3. Memories attached to NSF3 as working memories cannot be used by any other accelerators. HWSEQ or HWSEQ SW override settings are ignored for those memories. 0x0: No working memory attached to NSF3. NSF3 cannot be used. 0x1: IMX A + B coefficient memories used. 0x2: Image buffers a, b, c, and d used. Those image buffers cannot be used for other purposes. This setting has higher priority than the context configuration	RW	0x0
29	RESERVED		R	0x0
28	LDC_R_BURST_BREAK	Controls if bursts issued by the LDC2 bridge could cross burst length boundaries. When this register is set, the LDC2 bridge only issues aligned bursts. Register can only be used when LDC_R_MAX_BURST_LENGHT is 32, 64 or 128 bytes. 0x0: Yes. 0x1: No. OCP transactions must be split	RW	0
27:26	LDC_R_MAX_BURST_LENGHT	Limits the maximum burst length that could be used by the LDC2 bridge 0x0: 8x128 0x1: 6x128 0x2: 4x128 0x3: 2x128	RW	0x0
25	RESERVED	Read returns 0.	R	0
24:21	LDC_R_TAG_CNT	Limits the maximum number of outstanding requests to LDC_R_TAG_CNT+1	RW	0x3
20	RESERVED	Read returns 0.	R	0
19:16	LDC_R_TAG_OFST	First OCP tag ID that can be used by LDC reads. It is SW's responsibility to prevent overlap with tags generated by the SIMCOP DMA Typically this value should be equal to SIMCP_DMA_CTRL.TAG_CNT+1	RW	0xC
15	RESERVED	Read returns 0.	R	0
14	IMX_B_CMD	Switch for IMX # command memory 0x0: Coprocessor bus 0x1: IMX B instruction read / write	RW	0
13:12	IMX_A_CMD	Switch for IMX A command memory 0x0: Coprocessor bus 0x1: IMX A instruction read / write 0x2: IMX B instruction read / write	RW	0x0
11	HUFF	Switch for Huffman table 0x0: Coprocessor 0x1: VLCDJ Huffman table read	RW	0
10	QUANT	Switch for quantization table 0x0: Coprocessor bus 0x1: VLCDJ quantization table read	RW	0
9	RESERVED	Read returns 0.	R	0
8	LDC_LUT	Switch for LDC LUT 0x0: Coprocessor bus 0x1: The LDC module could access the LDC LUT.	RW	0

8.4.2 ISS SIMCOP Hardware Sequencer and Buffers Module

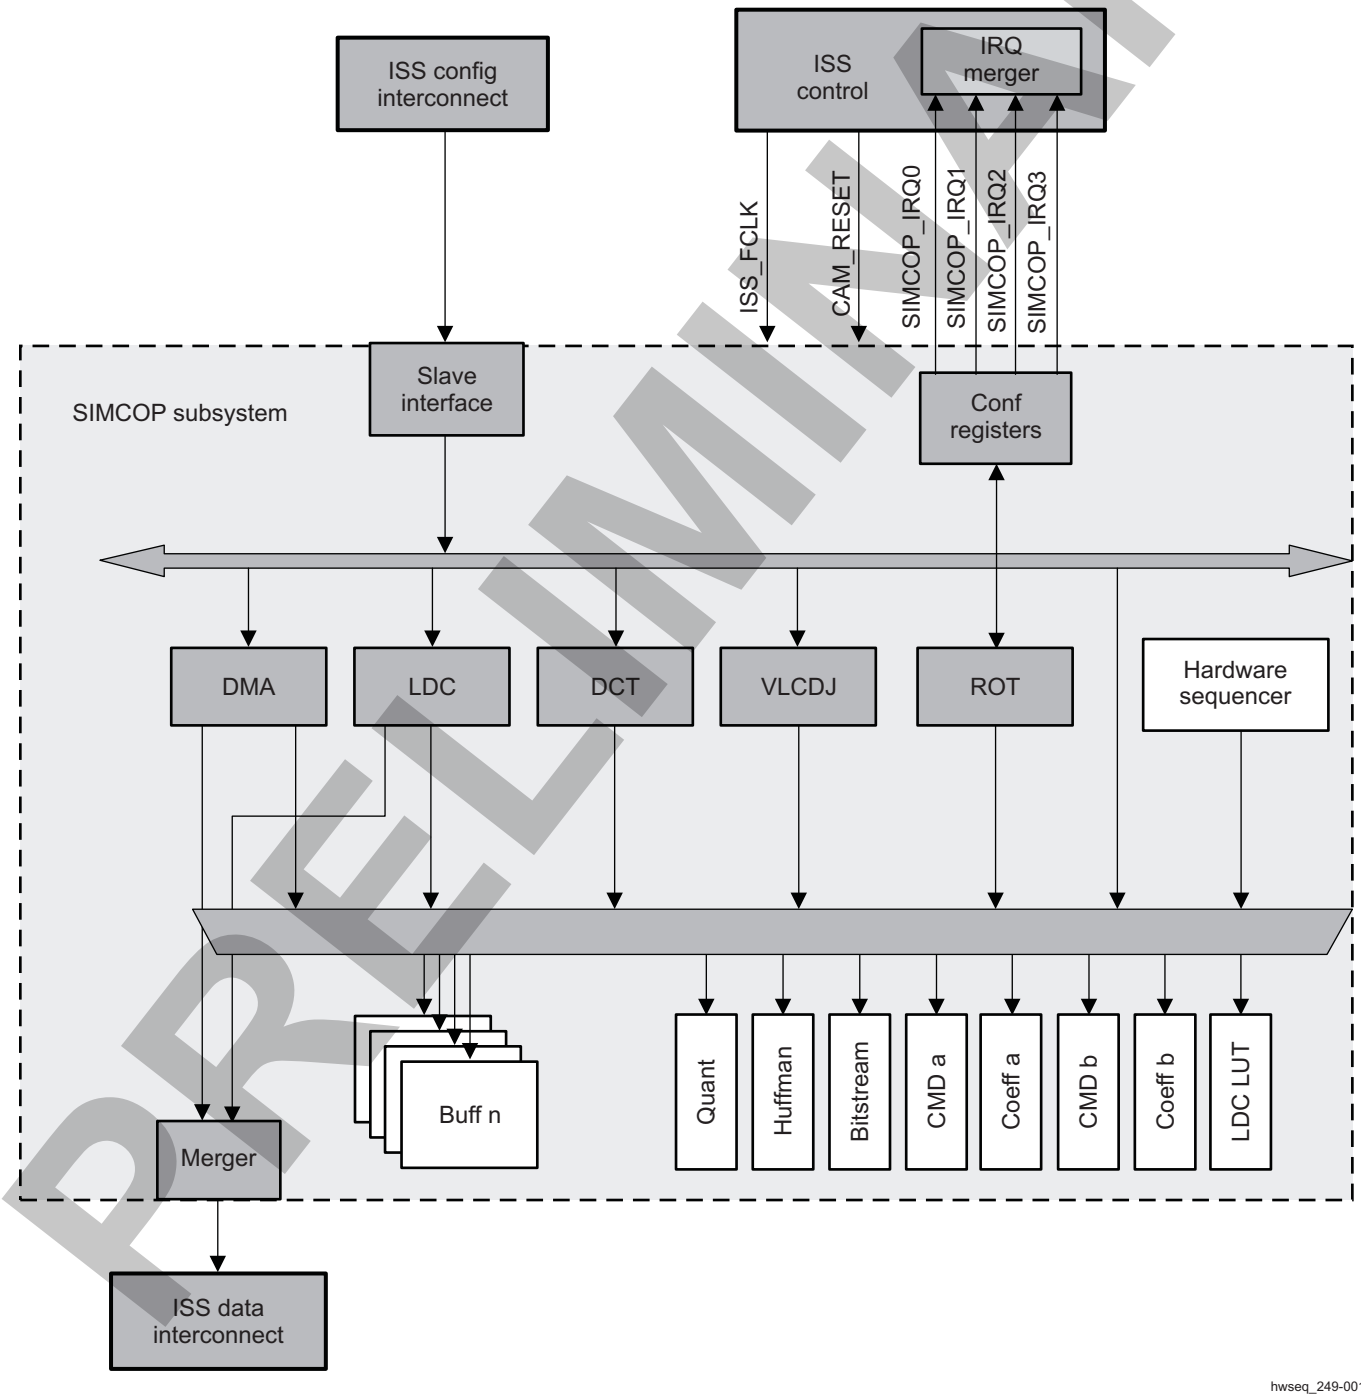
This section describes the hardware sequencer and buffers in the still image coprocessor (SIMCOP) subsystem.

8.4.2.1 ISS SIMCOP Hardware Sequencer and Buffers Overview

The SIMCOP hardware sequencer control all the modules included in the SIMCOP subsystem with their memories.

Figure 8-260 shows an overview of the hardware sequencer and buffers in the SIMCOP subsystem.

Figure 8-260. Hardware Sequencer and Buffers in the SIMCOP Subsystem



PRELIMINARY

- Hadrware acceleration for low-level sequencing tasks:
  - Synchronizes with DMA, DCT, VLCD, ROT, LDC
  - Supports 4 memory crossbar contexts
- On chip memories (RAM):
  - 8 image buffers, 4 KiB each
  - Quantization table storage: 512 bytes
  - Huffman table storage: 4 KiB
  - Bitstream buffer: 4 KiB
  - LDC look-up table storage: 256 entries
- Power management support

8.4.2.2 ISS SIMCOP Hardware Sequencer and Buffer Integration

The hardware sequencer and buffers module is part of the SIMCOP subsystem in the ISS.

Figure 8-261 shows the integration of the hardware sequencer and buffers in the SIMCOP subsystem.

8.4.2.3 ISS SIMCOP Hardware Sequencer and Buffers Functional Description

8.4.2.3.1 ISS SIMCOP Hardware Sequencer and Buffers Software Reset

For information about how to perform a software reset, see Section 8.4.1.2.2, *Software Reset*.

8.4.2.3.2 ISS SIMCOP Hardware Sequencer and Buffers Power Management

For more information about power management, see Section 8.4.1.2.1.3, *ISS SIMCOP Power Management*.

8.4.2.3.3 ISS SIMCOP Hardware Sequencer and Buffer Interrupt Requests

This module sends four interrupts to the ISS top level. For more information about interrupt management, see Section 8.4.1.2.3, *Interrupt Merger*.

8.4.2.3.4 ISS SIMCOP Hardware Sequencer Buffer Description

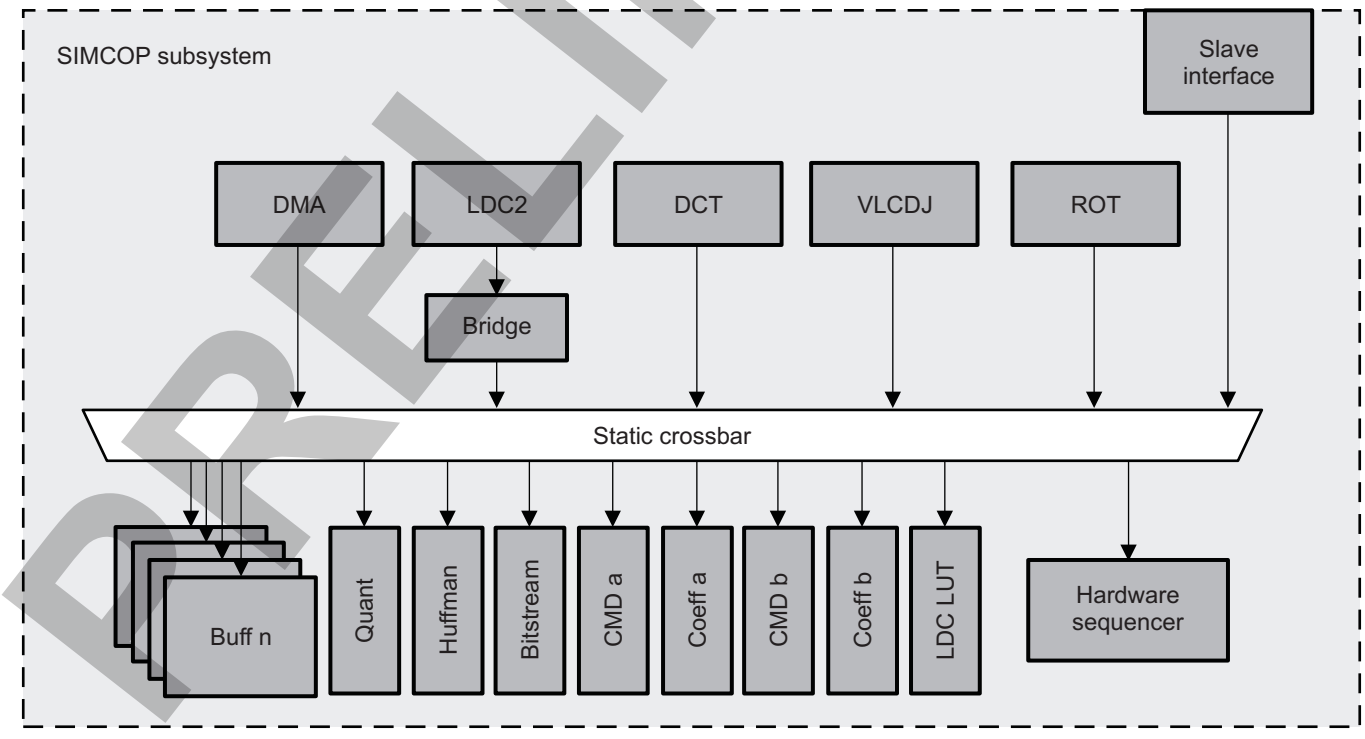
The SIMCOP subsystem includes the following memories:

- Eight image buffers: 4 KiB each
- Quantization table storage: 512 bytes
- Huffman table storage: 4 KiB
- Bitstream buffer: 4 KiB
- LDC lookup tables storage: 256 entries
- LDC private working memory

8.4.2.3.4.1 Static Crossbar

The static crossbar connect SIMCOP modules to the SIMCOP memories as shown in Figure 8-262.

Figure 8-262. SIMCOP Static Crossbar Overview



hwseq_249-002

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The buses for QUANT, HUFF, LDC LUT, CMD a, and CMD b are controlled by the CPU. Typically, those memories are initialized before the SIMCOP starts processing and the content remains unchanged until the full frame is processed. The amount of data transferred to those memories is low and transfer is not timing critical. Table 8-1379 shows how to connect these memories to the SIMCOP modules.

NOTE: The transfer can only be done through the slave interface (that is, the CPU or system DMA). The SIMCOP DMA can not access those memories.

Table 8-1379. Static Crossbar Control Summary

Memory	Register SIMCOP_CTRL	Value				
		Bus	VLCDJ HUFF	VLCDJ QUANT	LDC LUT	LDC INPUT
Quantization	[10] QUANT	0		1		
Huffman	[11] HUFF	0	1			
LDC LUT	[8] LDC_LUT	0			1	
LDC Priv	[7:6] LDC_INPUT					3

Image buffers and coefficient memories are used to store the data to be processed and processing results. Those memories can be accessed by the SIMCOP DMA, SIMCOP bus, and SIMCOP modules. Table 8-1380 shows possible connections in the SIMCOP static crossbar. For example, the DCT Freq port could access image buffer a when SIMCOP_HWSEQ_SWITCH_i[2:0] IMBUFF_A = 5 (i = 0, 1, 2, or 3 corresponds to the active context).

The SIMCOP supports multiple contexts for the configuration of those memories. Software or the hardware sequencer can activate different contexts.

The BITSTREAM data flow is asynchronous from the macroblock pipeline, therefore, it supports dynamic buffer switching logic.

Table 8-1380. Static Crossbar Control Summary (2/2)

Memory	Register (SIMCOP_HWSEQ_STEP_SWITCH_i and SIMCOP_HWSEQ_STEP_CTRL2_i)	Value									
		Bus	DMA	VLCDJ IO	VLCDJ BS	DCT Spatial	DCT Freq	LDC 0	LDC WMEM	ROT In	ROT Out

IMBUF h	[31:28] IMBUFF H	0	1	4		5	6	9			7
Bitstream	Handled by hardware	X	X				X				

8.4.2.3.4.2 Image Buffers

Image buffers are 4 banks × 256 × 32 bits (4K bytes) working memories used by the SIMCOP modules to perform image processing operations. Image buffers are shared between the DCT, LDC, VLCDJ, ROT, DMA, and SIMCOP bus accesses. All initiators cannot access the image buffers simultaneously.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

Switches are controlled by the hardware sequencer or an external initiator through register configuration. Data is always organized in little endian form.

One or multiple image buffers can be attached to a given accelerator port by configuring the appropriate bits in the SIMCOP_HWSEQ_STEP_SWITCH_i registers.

The image buffer address mapping to different busses shown in Table 8-1381 is controlled using the appropriate SIMCOP_HWSEQ_STEP_CTRL_i register bit fields.

Table 8-1381. Image Buffer Address Map

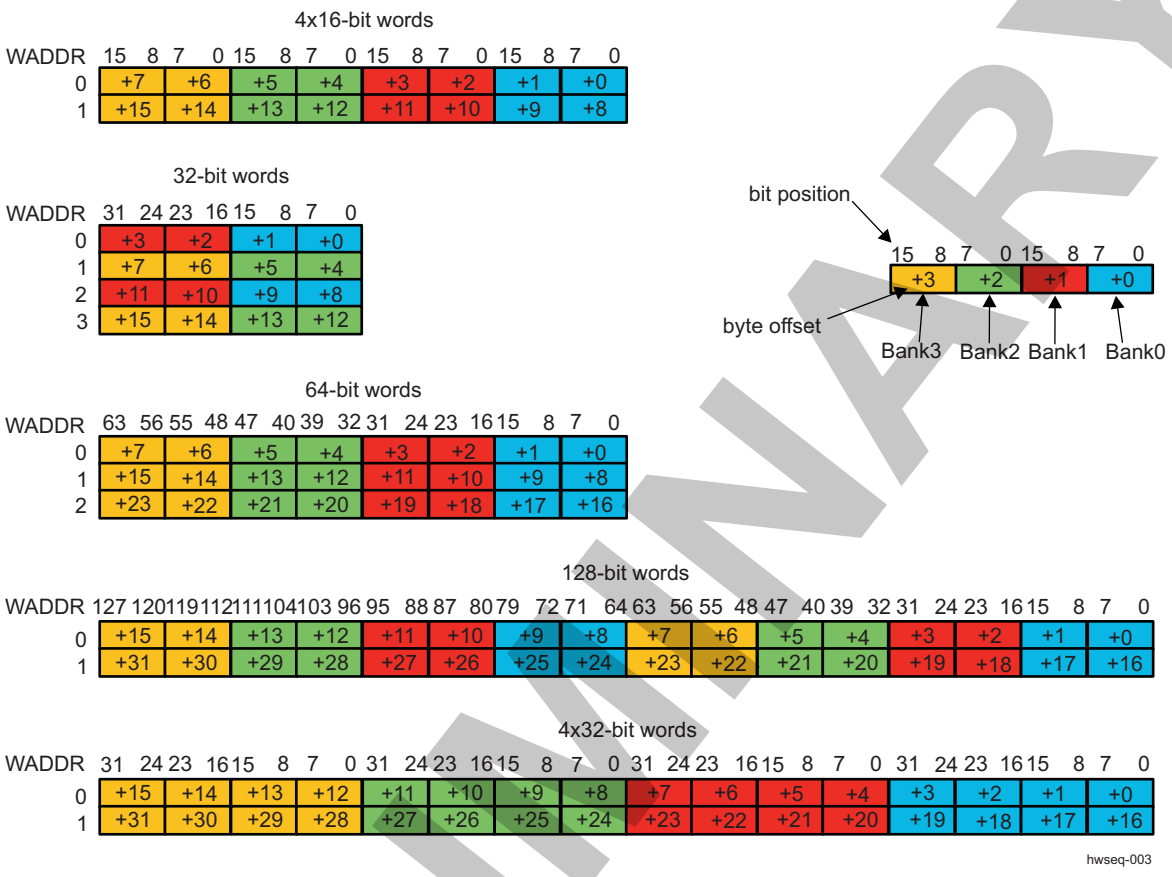
Figure 8-263. Image Buffer Width Translation



8.4.2.3.4.3 Quantization Memories

The QUANT memory is used to store the quantization and dequantization tables for the VLCDJ module.

Coefficients are coded as 16-bit values. Every color component requires 8 × 8 quantization entries, therefore the QUANT memory of SIMCOP can hold up to four tables as shown in Table 8-1382.

Table 8-1382. Quantization Table Storage in QUANT Memory

Table	0	1	2	3
ADDR	0x000	0x0080	0x0100	0x0180
Encode only	Y quantization	UV quantization	Unused	Unused
Decode only	Unused	Unused	Y dequantization	UV dequantization
Encode and decode	Y quantization	UV quantization	Y dequantization	UV dequantization

The QUANT memory is shared between the VLCDJ and SIMCOP bus accesses. All initiators cannot access QUANT simultaneously.

The initiators access types to the QUANT memory are summarized in Table 8-1383. QUANT memory configuration depends on the initiators.

8.4.2.3.4.4 Huffman Tables

The HUFF memory is used to store the Huffman table for the VLCDJ module. Details about the Huffman table organization can be found in the VLCDJ module description, see Section 8.4.6, *VLCDJ* .

The HUFF memory is shared between the VLCDJ and SIMCOP bus accesses. All initiators cannot access the HUFF memory simultaneously.

The initiators access types to the HUFF memory are summarized in Table 8-1384. The HUFF memory configuration depends on the initiators.

Table 8-1384. HUFF Memory Organization

8.4.2.3.4.5 BITSTREAM Buffer

8.4.2.3.4.5.1 Overview

The BITSTREAM buffer is used to store the VLCDJ bit stream. The BITSTREAM buffer is shared between the VLCDJ, DMA, and SIMCOP bus accesses.

The BITSTREAM buffer can be used in manual or automatic mode.

In manual mode, software selects if the SIMCOP DMA, VLCDJ Bit Stream port, or SIMCOP bus can access the BITSTREAM buffer. Manual mode is typically used to interleave JPEG encode and decode, for example to support JPEG transcoding. .

In automatic mode (SIMCOP_HWSEQ_CTRL[6:4] BITSTREAM = ENCODE or DECODE) the BITSTREAM buffer is handled as two banks to prevent access collision between the VLCDJ and SIMCOP DMA. A dedicated hardware engine (BBM) is used to guarantee that the VLCDJ and SIMCOP DMA access separate banks.

Automatic mode is disabled by writing SIMCOP_HWSEQ_CTRL[6:4] BITSTREAM = COPR.

The BITSTREAM buffer mapping into the SIMCOP DMA address map depends on the SIMCOP_HWSEQ_CTRL[6:4] BITSTREAM, SIMCOP_HWSEQ_CTRL[3:2] BITSTR_XFER_SIZE registers and the internal state of the BBM. Table 8-1385 shows the mapping of bitstream buffer for the SIMCOP DMA.

Table 8-1385. BITSTREAM Buffer Mapping to SIMCOP DMA

SIMCOP_HWSEQ_CTRL		Address Map		BBM count	Bitstream buffer

				7	0x700	0x7FF
		0x1100	0x1FFF	N/A	N/A	N/A

8.4.2.3.4.5.2 Automatic BITSTREAM Buffer Management

To enter automatic mode, software must write the following values into the BITSTREAM configuration register:

- SIMCOP_HWSEQ_CTRL[6:4] BITSTREAM = COPR (required to reset BBM)
- SIMCOP_HWSEQ_CTRL[6:4] BITSTREAM = JPEG_ENCODE or JPEG_DECODE

8.4.2.3.4.6 LDC Lookup Table

The LDC_LUT memory is used to store lookup tables for the LDC module. The LDC_LUT is shared between the LDC and SIMCOP bus accesses. All initiators cannot access LDC_LUT simultaneously.

The initiators access types to the QUANT memory are summarized in Table 8-1386. QUANT memory configuration depends on the initiators.

Table 8-1386. LDC_LUT Memory Organization

RESERVED								LDC_LUT [2a+1]								RESERVED								LDC_LUT [2a+0]							

8.4.2.3.4.7 LDC Private Input Memory

The LDC has a private input memory that can be used when the LDC operates in YUV4:2:0 mode. For YUV4:2:2 and RAW operation, the LDC must use image buffers as input memories.

The LDC input memory is dedicated for LDC operation. It cannot be accessed from the SIMCOP bus or by any other SIMCOP module.

8.4.2.3.5 ISS SIMCOP Hardware Sequencer

The SIMCOP typically processes a full frame on a macroblock-by-macroblock basis. The SIMCOP modules and the DMA controller trigger an interrupt when they have completed a macroblock. This event can either trigger an interrupt to an external initiator (CPU) (manual mode) or trigger a context switch and resume DMA/SIMCOP module processing. Typically, initiator intervention is needed to fill the macroblock pipeline (called pipe-up, that is, the first n macroblocks of an image) and to flush the macroblock pipeline (called pipe-down, that is, the last n macro-blocks of an image). Automatic sequencing mode is typically used for the rest of the image.

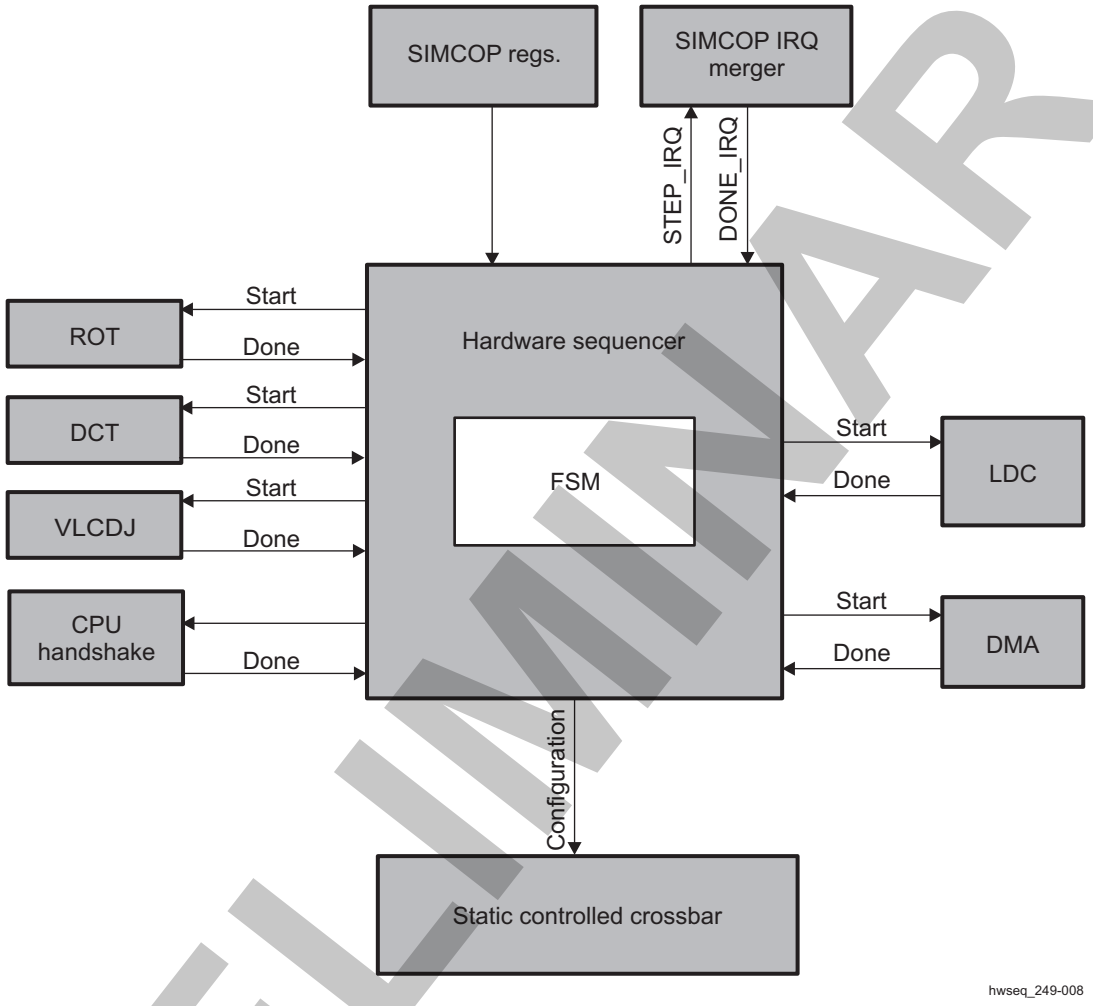
PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The hardware sequencer is particularly useful to offload the initiator during JPEG encoding/decoding, ROT or LDC processing.

Figure 8-264 depicts the SIMCOP hardware sequencer overview.

Figure 8-264. SIMCOP Hardware Sequencer Overview



The hardware sequencer can automatically execute a predefined number of sequencing steps without software intervention. This is called automatic operation. Automatic operation can also be used for pipeline filling and flushing with some limited software intervention. During automatic operation, the hardware sequencer controls the generation of START/DONE pulses and the connections in the static controlled crossbar. Software can take control over some resources while the hardware sequencer is running. This is called hardware sequencer override.

8.4.2.3.5.1 Automatic Operation

Figure 8-265 shows the flow diagram executed by the hardware sequencer.

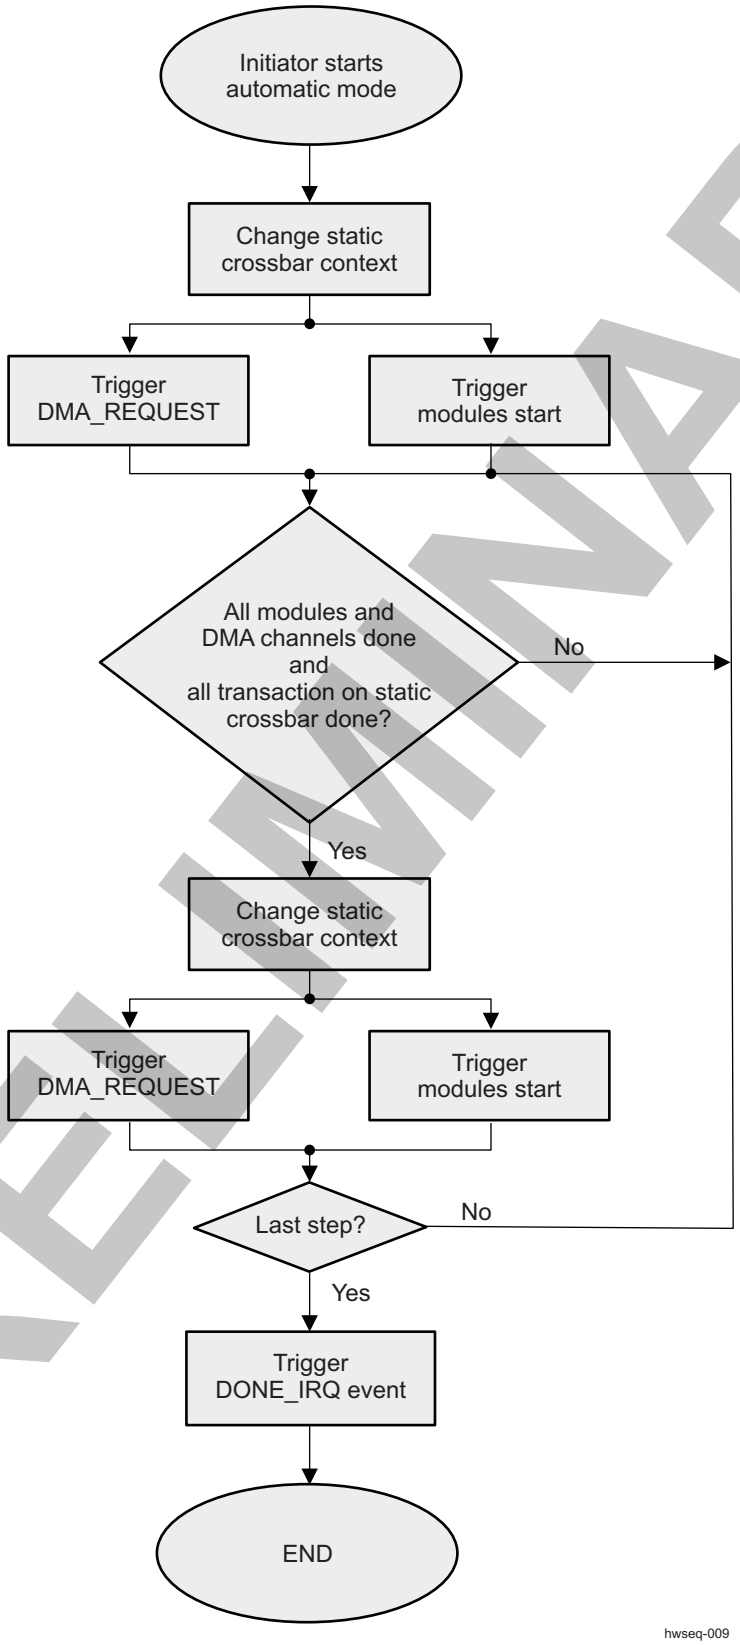
Figure 8-265. Hardware Sequencing Example



PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The external initiator configures the different SIMCOP modules and DMA channels. When this is complete, it enables the hardware sequencer. This resets the internal state of the hardware sequencer (pending events and context switch counter).

It starts by running sequence step SIMCOP_HWSEQ_CTRL[12:11] STEP:

- Clear all pending completion events that have been selected for Step 0 in the hardware sequencer. Note: This does not affect the SIMCOP_IRQSTATUS register.
- Apply step SIMCOP_HWSEQ_CTRL[12:11] STEP configuration to the static crossbar
- Start DMA transfers. Multiple channels can be enabled sequentially (that is, YUV4:2:0 data transfers or SIMCOP-SDRAM followed by SDRAM-SIMCOP) by using the SIMCOP DMA linking feature.
- Start hardware accelerators. The list of accelerators to start can be selected by software using the SIMCOP_HWSEQ_STEP_CTRL_i[7:0] *_SYNC register

The hardware sequencer then waits for completion of events from the selected SIMCOP modules and SIMCOP DMA channels.

The hardware sequencer also ensures that all SIMCOP memory accesses requested by the accelerators and DMA channels enabled for the synchronization step have completed. This condition prevents data corruption due to early switching.

Steps can be chained to define the sequence to execute. Steps are started until the step counter reaches the limit defined by software. When the last step has completed, a DONE_IRQ event is triggered.

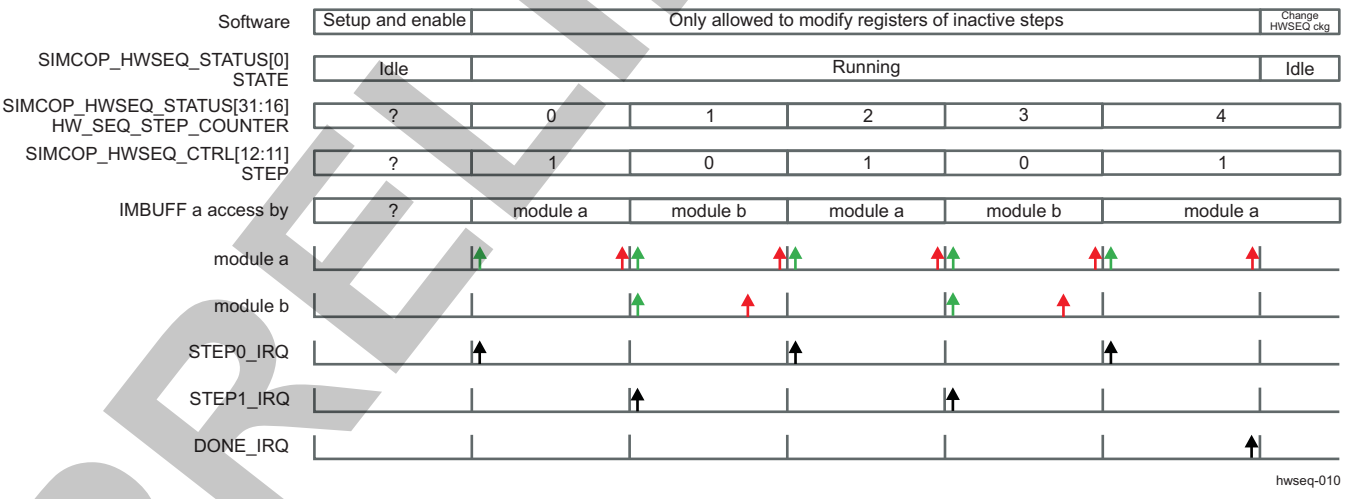
The SIMCOP can execute one hardware sequence at the time. However, software can be used to execute multiple independent sequences in parallel (that is, two unrelated macroblock pipelines) using the override feature.

The hardware sequencer has no specific support for macroblock pipeline filling (pipe-up) or flushing (pipe-down). It needs some software intervention.

The hardware sequencer supports sequences composed of up to four steps. Longer sequences require software intervention.

Figure 8-265 illustrates the hardware sequencer operation.

Figure 8-266. Hardware Sequencer Operation Example



The example involves utilization of two SIMCOP modules (or DMA channels) that are synchronized using the hardware sequencer. A total of five sequencing steps are executed (SIMCOP_HWSEQ_CTRL[31:6] HW_SEQ_STEP_COUNTER=5). The sequence is 2 steps long and starts with Step 1. Those two steps are configured using the SIMCOP_HWSEQ_STEP_*_i registers(where i = 0 and 1).

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The SIMCOP modules processing is started using START pulses (green). When the SIMCOP modules are done, they return a DONE pulse (red). Software can choose which accelerators to run for a given step using the SIMCOP_HWSEQ_STEP_CTRL_i[7:0] *_SYNC registers. They do not need to finish at the same time because the hardware sequencer waits for reception of all DONE pulses of used accelerators before moving to the next step.

The hardware sequencer also triggers a series of interrupts that can be used by software. It is possible, for example, for software to change the configuration of inactive sequencing steps. This can be particularly useful to run longer sequences than what is supported by hardware.

For example, software can setup a 4-step long looping sequence: Step 0 → 1 → 2 → 3 → 0 → 1 → .... When the STEP1_IRQ event is triggered, software can load the configuration to be used next time Step 0 becomes active in the SIMCOP_HWSEQ_STEP_*_i registers.

8.4.2.3.5.2 Hardware Sequencer Override

By default, the hardware sequencer controls START/DONE pulses of all SIMCOP modules as well as the static controlled crossbar. Software can take the control over some resources by setting the appropriate bits in the SIMCOP_HWSEQ_OVERRIDE register. Sequencing resources under software control are managed using the SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE and SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE registers.

Changes done to the SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE[27:11] *_OFST and SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE registers have immediate effect. It is the responsibility of software to ensure there is no active traffic on the impacted connection in the static controlled crossbar.

For example, when software wants to alternatively attach image buffers a and b to SIMCOP_DMA while preserving the buffer start address in the SIMCOP DMA address map constant it sets:

- SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE[2:0] IMBUFF_A = 1
- SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE[6:4] IMBUFF_B = 1

for the full application duration. It then changes the SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE[2:0] IMBUFF_A and SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE[6:4] IMBUFF_B registers to attach the image buffers to the correct SIMCOP submodule.

The settings in the SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE and SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE registers for resources controlled by the hardware sequencer have no effect.

Synchronization with SIMCOP submodules is controlled using the SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE[7:0] *_TRIGGER bit fields. For the ROT, VLCDJ, DCT, and LDC, a START pulse is sent to the module when a 1 is written into the appropriate bit field. Software can trigger one or multiple start pulses at the time. The *_TRIGGER bit field is cleared by writing 1. It is automatically set by hardware when a DONE pulse is received from the relevant SIMCOP submodule.

Software can poll the status of the SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE[7:0] *_TRIGGER bit fields to detect when a SIMCOP module has completed its processing task. Alternatively, software can also use an interrupt. SIMCOP has the capability to merge one or multiple internal events into SIMCOP outgoing interrupts. Software can choose between two modes for each interrupt output (SIMCOP_CTRL[3:0] IRQx_MODE):

- 0x0 : OR, the interrupt is asserted when one of the selected events has occurred
- 0x1 : AND, the interrupt is asserted when all selected events have occurred

The AND mode leads to a lower initiator load. In fact, the initiator is only interrupted once per sequencing step even when events from multiple SIMCOP submodules are expected. Also, it does not need to poll the SIMCOP_HL_IRQSTATUS_i register to detect which events have occurred, it simply needs to write 0xFFFFFFF into the SIMCOP_HL_IRQSTATUS_i register to clear all pending events.

The SIMCOP DMA START/DONE control is slightly different. Software can trigger one or multiple DMA channels by writing into the SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE[7:5] DMA_TRIGGER bit field. The DMA_TRIGGER bit field returns the written value when all expected DONE pulses have been received from SIMCOP DMA.

Alternatively, SIMCOP modules (except the LDC) may be triggered by direct writes into their configuration registers. However, this approach lead to higher initiator load because multiple writes must be done.

8.4.2.4 ISS SIMCOP Hardware Sequencer and Buffers Basic Programming Model

8.4.2.4.1 ISS SIMCOP Hardware Sequencer and Buffers Application Programming Principle

Software must first configure the SIMCOP access tag handling (SIMCOP_CTRL[24:21] LDC_R_TAG_CNT, SIMCOP_CTRL[19:16] LDC_R_TAG_OFST, and SIMCOP_DMA_CTRL[7:4] TAG_CNT). Software must ensure there is no active traffic on the SIMCOP master port before changing those registers.

Then it initializes the Huffman, Quantization, and LDC LUT if they are used. Those memories must first be attached to the SIMCOP bus so that they can be accessed from the slave port (SIMCOP_CTRL[11] HUFF, SIMCOP_CTRL[10] QUANT, and SIMCOP_CTRL[7:6] LDC_LUT). Then they can be preloaded using either an external CPU or an external DMA engine. SIMCOP DMA cannot preload those tables.

Similarly, software can also preload data like filter coefficients into image buffers. This can be handled by the SIMCOP DMA:

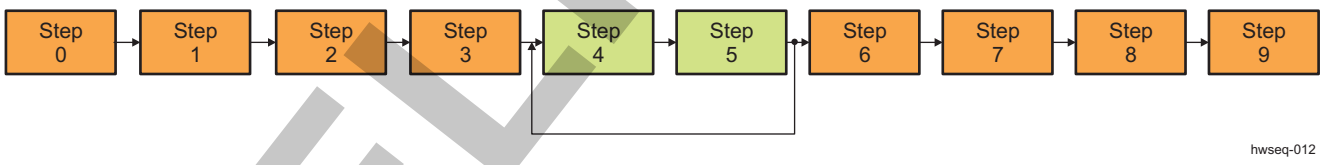
- The buffers must first be attached to the SIMCOP DMA using the SIMCOP_HWSEQ_OVERRIDE and SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE registers.
- Alternatively, software can use the SIMCOP_HWSEQ_STEP_*_0 registers instead of the override feature. The hardware sequencer ensures that the configuration of Step 0 is applied when the hardware sequencer is disabled.
- Software then configures and starts one or multiple data transfers using the SIMCOP DMA.
- Software monitors SIMCOP DMA events to know when DMA transfers are complete. Other configuration tasks may happen concurrently, but software must ensure that transfers have completed before attaching the memories to another module.

It must then enable the modules going to be used.

Typically, the first and last steps of the macroblock pipeline are different from those in the middle of the pipeline. The hardware sequencer has no specific support for pipe-up and pipe-down. However, software cancut the sequence into smaller ones to still benefit from the hardware sequencing and to avoid software sequencing.

Figure 8-267 shows an example of a 10-step sequence involving two DMA transfers and three modules.

Figure 8-267. Typical Hardware Sequencer Controlled Sequencer With Pipe-Up and Pipe-Down



The macroblock pipeline is composed of a chain of three accelerators. Data between modules is exchanged using ping-pong buffering.

Pipe-up and pipe-down require four sequencing steps each. The main processing can be done with two steps.

Software configures the hardware sequencer with the four step pipe-up sequence. Each step is executed once. When pipe-up is done, the SIMCOP triggers the DONE_IRQ event.

Software then reconfigures the hardware sequencer for the two step main sequence. The number of steps is defined by the amount of data to process. When the main pipe is done, the SIMCOP triggers the DONE_IRQ event.

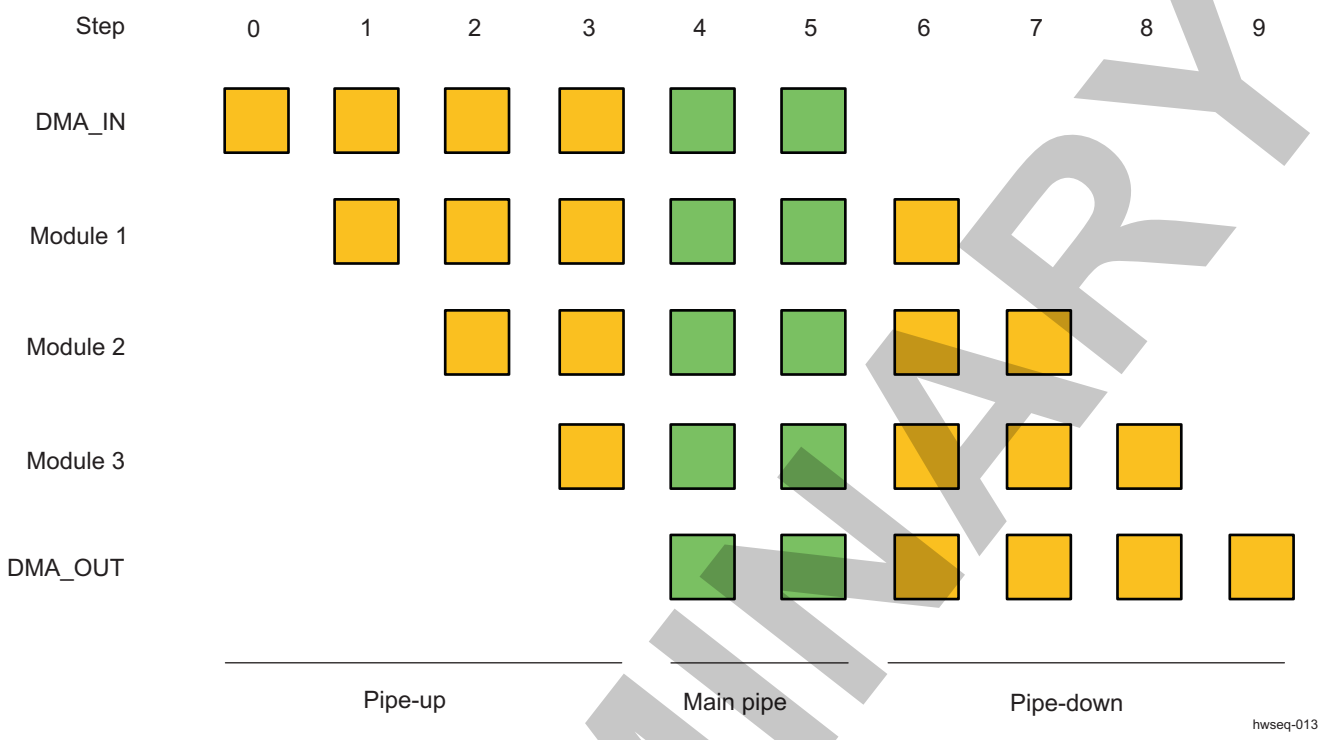
Software finally reconfigures the hardware sequencer with the four step pipe-down sequence. Each step is executed once. When pipe-down is done, the SIMCOP triggers the DONE_IRQ event.

Figure 8-268 shows an example of pipe-up and pipe-done.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 8-268. Pipe-Up and Pipe-Down



The hardware sequencer configuration determines which module can access a given SIMCOP memory for a sequence step.

8.4.2.4.2 External CPU Use for Data Processing

An external CPU can be used to perform some data processing as the SIMCOP hardware accelerators do. A similar mechanism to the START/DONE pulse interaction with the SIMCOP hardware accelerators is implemented.

The external CPU receives the request to start processing by the CPU_PROC_START_IRQ interrupt merged at the SIMCOP subsystem level. This interrupt is enabled and acknowledged as usual.

When processing has completed, the CPU generates the DONE pulse to the hardware sequencer by writing 1 into the SIMCOP_HWSEQ_CTRL[10] CPU_PROC_DONE register.

8.4.2.4.3 Rotation Operational Mode Configuration

The macroblock pipeline is controlled by a two step hardware sequence:

8.4.2.4.4 LDC Operational Mode Configuration

The LDC module fetches data from system memory, performs the transformation, and stores results into image buffers. The DCT and VLCDJ modules are used to JPEG compress this data and store the results to the BITSTREAM buffer. The SIMCOP DMA is used to transfer compressed data from the BITSTREAM buffer to system memory.

8.4.2.4.5 Concurrent Software and Hardware Sequencing

Software can perform sequencing tasks concurrently to hardware sequencing. This is supported through the hardware sequencer override registers:

- SIMCOP_HWSEQ_OVERRIDE
- SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE
- SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE
- SIMCOP_HWSEQ_STEP_CTRL2_OVERRIDE

  Software can select which hardware resources are controlled by the hardware sequencer and what resources are controlled by software. Configuration parameters for software-controlled resources are provided using those registers as well.

15:13	RESERVED	Read returns 0.	R	0x0
12:11	STEP	This register is automatically updated by the HW sequencer when it is active. Otherwise, SW could use it to activate the content of a given set of step registers (SIMCOP_HWSEQ_STEP_i).	RW	0x0
10	CPU_PROC_DONE	Used by the CPU to tell that it has completed data processing. This feature should be used together with the CPU_PROC_START_IRQ event Read's always return 0. Write 0x0: No effect. Write 0x1: CPU processing completed.	W	0
9:8	BBM_SYNC_CHAN	Defines the SIMCOP DMA HW synchronization channel to be used for BBM. This register is only used when BITSTREAM=ENCODE or DECODE. SW must ensure that the same DMA HW synchronization channel isn't used by the HW sequencer.	RW	0x0
7	BBM_STATUS	Status of the Bitstream buffer management HW. Used only during automatic mode [BITSTREAM=5 or 6] Equals 0 (IDLE) in manual mode [BITSTREAM=0..4]. Set when automatic mode is entered. Automatic encode mode: used to detect when all banks have been flushed after the processing has completed (i.e. but request bank signals have been de-asserted by BBM). Automatic decode mode (BITSTREAM=DECODE): returns to 0 (IDLE) when automatic mode is left (BITSTREAM=COPR). Read 0x1: BBM is busy. Read 0x0: BBM is idle	R	0
6:4	BITSTREAM	BITSTREAM buffer access control 0x0: Bank 0: coprocessor bus (0x1000-0x17FF) Bank 1: coprocessor bus (0x1800-0x1FFF) 0x1: Bank 0: DMA (0x1000-0x17FF) Bank 1: DMA (0x1800-0x1FFF) 0x2: Bank 0: VLCDJ.B (0x000-0x7FF) Bank 1: VLCDJ.B (0x800-0xFFF) 0x3: Bank 0: DMA (0x1000-0x17FF) Bank 1: VLCDJ.B (0x800-0xFFF) 0x4: Bank 0: VLCDJ.B (0x000-0x7FF) Bank 1: DMA (0x1800-0x1FFF) 0x5: The BITSTREAM buffer is managed by HW as a PING/PONG buffer to support JPEG encode use case. It could be accessed by the SIMCOP DMA or the VLCDJ module. The BITSTREAM HW sequence is reset when the mode is changed to COPR, VLCDJ or DMA. 0x6: The BITSTREAM buffer is managed by HW as a PING/PONG buffer to support JPEG decode use case. It could be accessed by the SIMCOP DMA or the VLCDJ module. The BITSTREAM HW sequence is reset when the mode is changed to COPR, VLCDJ or DMA.	RW	0x0

Bits	Field Name	Description	Type	Reset
3:2	BITSTR_XFER_SIZE	Defines the amount of data to be transferred per HW request to the SIMCOP DMA. Bigger sizes lead to better SDRAM efficiency but prevents fine grained DMA transfer arbitration. This register is only used by HW when BITSTREAM=ENCODE or BITSTREAM=DECODE. 0x0: 2048 bytes 0x1: 1024 bytes 0x2: 512 bytes 0x3: 256 bytes	RW	0x0
1	HW_SEQ_STOP	Stop the HW sequencer. This feature is typically used to recover from an error condition. Read's always return 0. Write 0x0: No effect. Write 0x1: Stop the HW sequence immediately (don't wait for expected DONE events). Setting this bit while the sequencer is idle has no effect.	W	0
0	HW_SEQ_START	Start the HW sequencer. Read's always return 0. Write 0x0: No effect. Write 0x1: Start STEP0 of the HW sequence. Setting this bit while the sequencer is running has no effect.	W	0

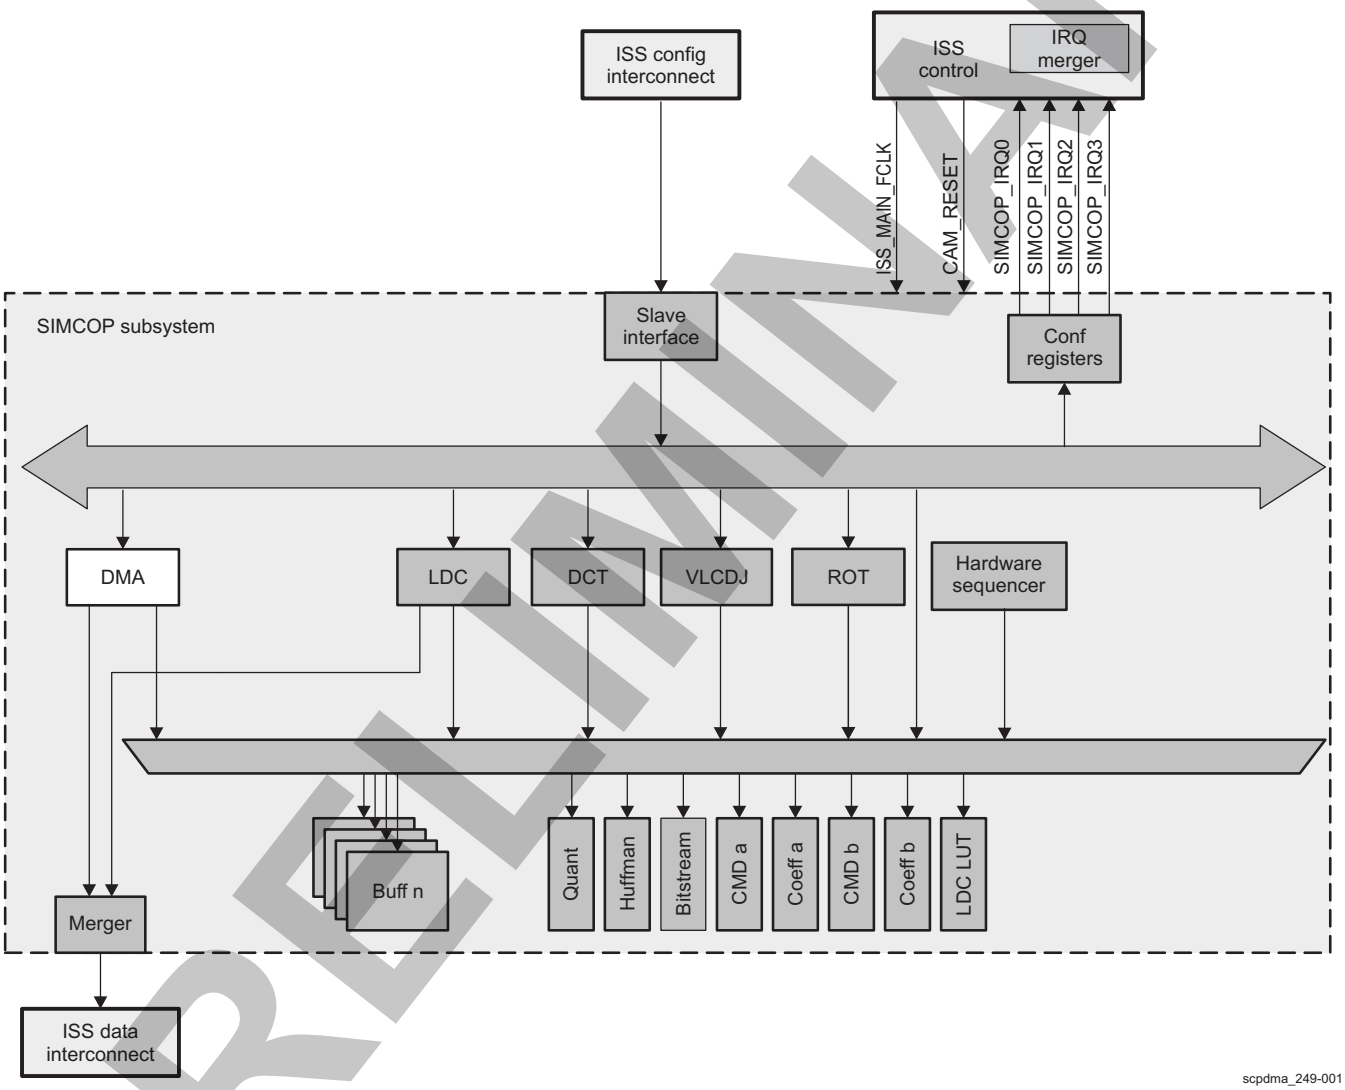
8.4.3 ISS SIMCOP DMA Module

This section describes the direct memory access (DMA) module in the still image coprocessor (SIMCOP) subsystem.

8.4.3.1 ISS SIMCOP DMA Overview

The direct memory access (DMA) module transfers data from system memory to the still image coprocessor (SIMCOP) memories and from SIMCOP memories. Figure 8-271 is an overview of the DMA module in the SIMCOP subsystem.

Figure 8-271. DMA in the SIMCOP Subsystem



The SIMCOP DMA supports the following features:

- Configuration interface, for register access
- Image subsystem (ISS) data interconnect master interface, for system memory access
  - Supports 1-dimensional (1D) and 2-dimensional (2D) burst
- SIMCOP crossbar master interface, for SIMCOP memories access
- Eight logical channels supported
- Hardware synchronization support
- 2-dimensional (2D) addressing transfers

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- 2D data block transfer (base address, stride, height, width)
- Array of 2D block transfer support
- Performance: Software-controllable bandwidth limiter

The SIMCOP DMA is not a general-purpose DMA. It can perform only 16-byte aligned transfers and does not have access to the ISS configuration interconnect. SDMA must be used instead.

8.4.3.2 ISS SIMCOP DMA Integration

The DMA module is part of the SIMCOP subsystem in the ISS. Figure 8-272 shows the integration of the DMA in the SIMCOP sybsystem.

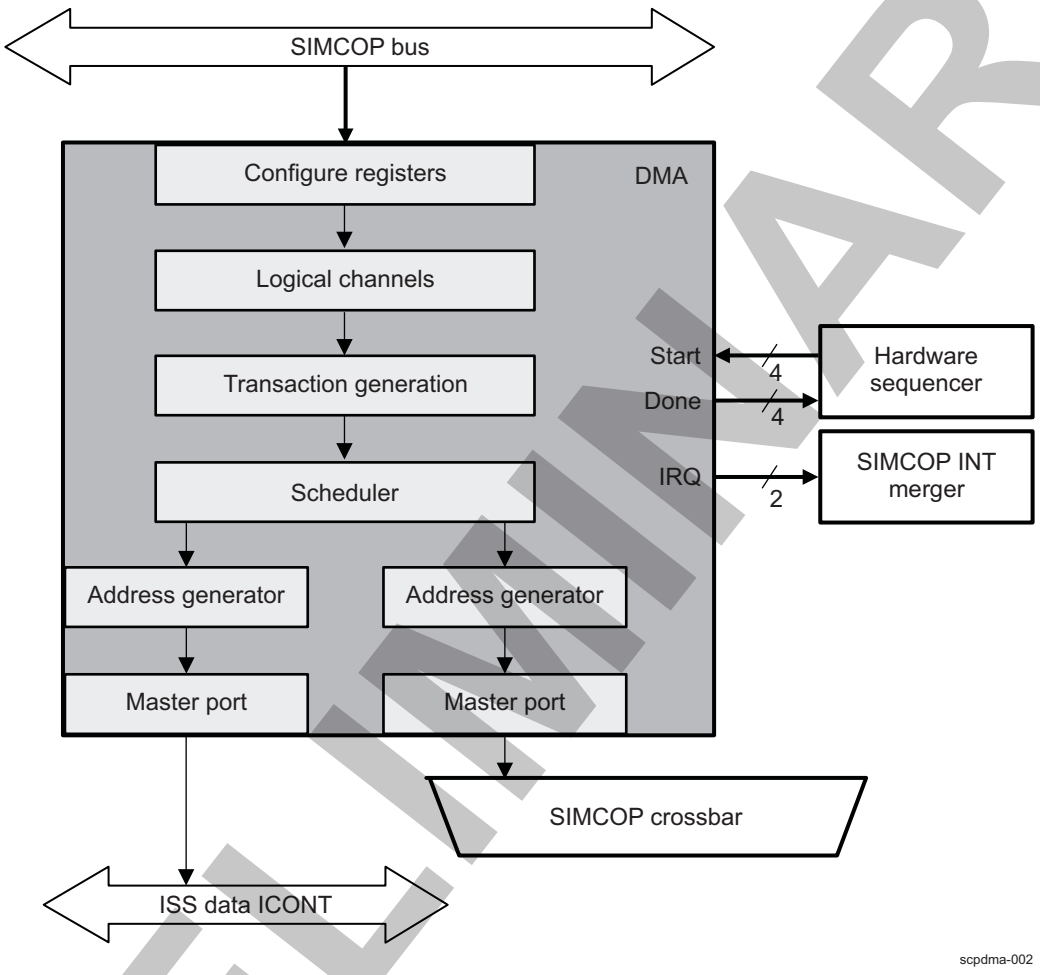
8.4.3.3 ISS SIMCOP DMA Functional Description

8.4.3.3.1 ISS SIMCOP DMA Block Diagram

Figure 8-273 is a block diagram of the SIMCOP DMA.

Figure 8-273. DMA Block Diagram



An external initiator sets up logical channels using the configuration interface.

When a logical channel becomes active, a transfer must be executed. A transfer corresponds to a 2D block of data copied from system memory to SIMCOP memory and vice versa.

A transfer is decomposed into one or multiple transactions by the transaction generation unit.

The scheduler issues transactions when tags are available. There can be one outstanding command per tag on the ISS data interconnect.

8.4.3.3.2 ISS SIMCOP DMA Power Management

Table 8-1414 lists the power-management features available in the DMA module.

Table 8-1414. Local Power-Management Features

8.4.3.3.3 ISS SIMCOP DMA Interrupt Requests

The SIMCOP DMA module can generate two interrupts, SIMCOP_DMA_IRQ0 and SIMCOP_DMA_IRQ1. These two interrupts are controlled by four registers:

- SIMCOP_DMA_IRQSTATUS_RAW_j: The status of the interrupt before masking
- SIMCOP_DMA_IRQSTATUS_j: The status of the interrupt after masking
- SIMCOP_DMA_IRQENABLE_SET_j: Enable an interrupt to propagate to SIMCOP_DMA_IRQi signal (unmask)
- SIMCOP_DMA_IRQENABLE_CLR_j: Disable an interrupt to propagate to SIMCOP_DMA_IRQi signal (mask)

To clear an interrupt, software must write 1 in the corresponding bit of the SIMCOP_DMA_IRQSTATUS_j register even if the event is not enabled (SIMCOP_DMA_IRQSTATUS_RAW_j is also cleared).

Table 8-1415 list all the SIMCOP DMA events that can lead to an interrupt generation.

Table 8-1415. SIMCOP DMA Events List

Bit Name	Bit	Event
BUS_ERR	0	Error occurred on bus
CHAN0_BLOCK_DONE_IRQ	16	Channel 0 has completed transfer of one 2D block.
CHAN1_BLOCK_DONE_IRQ	17	Channel 1 has completed transfer of one 2D block.
CHAN2_BLOCK_DONE_IRQ	18	Channel 2 has completed transfer of one 2D block.
CHAN3_BLOCK_DONE_IRQ	19	Channel 3 has completed transfer of one 2D block.
CHAN4_BLOCK_DONE_IRQ	20	Channel 4 has completed transfer of one 2D block.
CHAN5_BLOCK_DONE_IRQ	21	Channel 5 has completed transfer of one 2D block.
CHAN6_BLOCK_DONE_IRQ	22	Channel 6 has completed transfer of one 2D block.
CHAN7_BLOCK_DONE_IRQ	23	Channel 7 has completed transfer of one 2D block.
CHAN0_FRAME_DONE_IRQ	24	Channel 0 has completed transfer of the full frame.
CHAN1_FRAME_DONE_IRQ	25	Channel 1 has completed transfer of the full frame.
CHAN2_FRAME_DONE_IRQ	26	Channel 2 has completed transfer of the full frame.
CHAN3_FRAME_DONE_IRQ	27	Channel 3 has completed transfer of the full frame.
CHAN4_FRAME_DONE_IRQ	28	Channel 4 has completed transfer of the full frame.
CHAN5_FRAME_DONE_IRQ	29	Channel 5 has completed transfer of the full frame.
CHAN6_FRAME_DONE_IRQ	30	Channel 6 has completed transfer of the full frame.
CHAN7_FRAME_DONE_IRQ	31	Channel 7 has completed transfer of the full frame.

8.4.3.3.4 ISS SIMCOP DMA Logical Channels

In the context of the SIMCOP, multiple logical channels are required to offload the external initiator. Typical uses of multiple contexts are:

- Run a read transfer followed by a write transfer. When this transfer is complete, new input data is fetched from system memory and stored in the image buffers.
- Read or write YUV4:2:0 data from system memory; YUV4:2:0 data is stored in two different system memory buffers.

8.4.3.3.4.1 Logical Channel States

The SIMCOP DMA supports up to eight ((SIMCOP_DMA_HWINFO[2] CHAN+1) × 4) logical channels. Each logical channel can be configured and triggered separately.

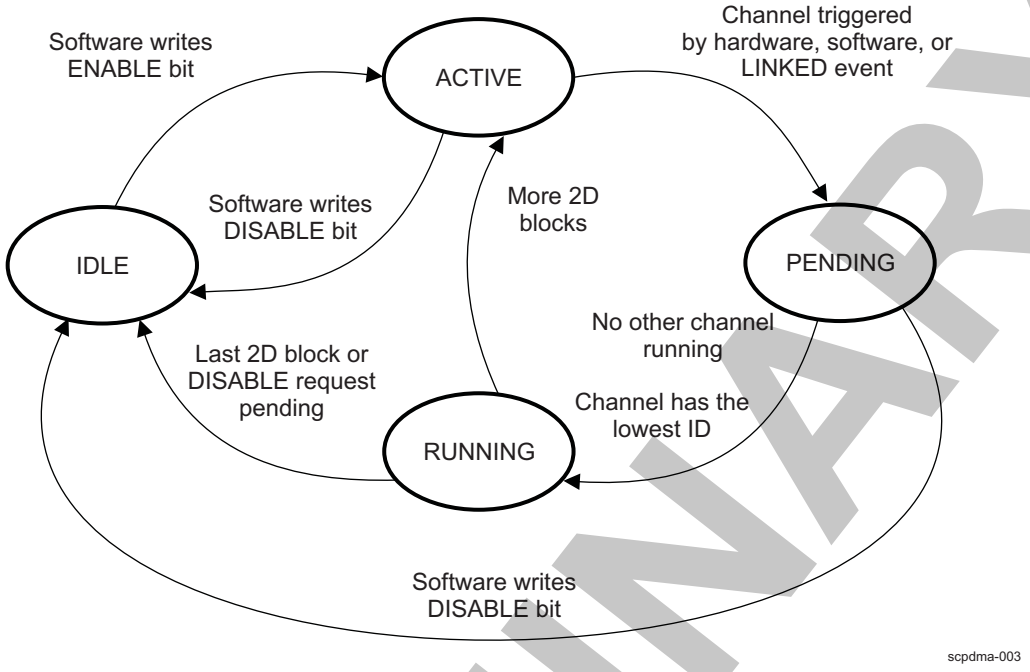
Idle logical channels must be configured and enabled (SIMCOP_DMA_CHAN_CTRL_i[0] ENABLE = 1) to be used.

Figure 8-274 shows the different states of a logical channel. Software can poll the current state from the SIMCOP_DMA_CHAN_CTRL_i[4:3] STATUS bit field.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

Figure 8-274. DMA Logical Channel States



When a trigger event is received by a channel in the ACTIVE state, it moves to the PENDING state. Trigger events received when the channel is in the IDLE, PENDING, or RUNNING state are discarded.

A logical channel is automatically disabled by hardware when a complete frame (all 2D blocks) is transferred. It can be disabled earlier by software by writing the SIMCOP_DMA_CHAN_CTRL_i[1] DISABLE bit. When a disable request occurs in the RUNNING state, it is memorized and executed when the channel leaves the RUNNING state. Pending disable requests have higher priority than channel trigger events.

When multiple logical channels are pending simultaneously, the following rules apply:

- An ongoing transfer of a 2D block is never stopped. It must complete before the next one starts.
- The logical channel with the lowest ID wins the arbitration (that is, CHAN0 has higher priority than CHAN1). Software can give higher priority to a channel by choosing a lower ID.

This situation can, for example, occur when software triggers a channel while a transfer is ongoing for another one. Two types of interrupts can be generated:

- CHANx_BLOCK_DONE_IRQ (where x = channel number): It is generated when the channel leaves the RUNNING state (RUNNING -> ACTIVE or RUNNING -> IDLE).
- CHANx_FRAME_DONE_IRQ (where x = channel number): It is generated when the channel enters the IDLE state.

8.4.3.3.4.2 Logical Channel Chaining, Trigger, and Hardware Synchronization

Active logical channels can be triggered:

- By software. Writes the SIMCOP_DMA_CHAN_CTRL_i[2] SWTRIGGER bit
- By a hardware DMA request. A channel can be made sensitive to a pulse on the START[y] input when SIMCOP_DMA_CHAN_CTRL_i[19:17] HWSTART = y has been configured by software.
- When the previous channel in the linked list finishes. This feature is enabled through the SIMCOP_DMA_CHAN_CTRL_i[16:12] LINKED bit field of the preceding channel in the chain.

When a channel completes, it can optionally send a pulse to the DONE[y] output. Software enables this feature by configuring SIMCOP_DMA_CHAN_CTRL_i[22:20] HWDONE = y.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Typically, the START + DONE synchronization mechanism is used together with the SIMCOP hardware sequencer. The hardware sequencer sends a pulse to START[y] a data transfer and the SIMCOP DMA responds with a DONE[y] pulse when the transfer completes. A transfer can be composed of one or multiple logical channels. For example, a YUV4:2:0-NV12 block copy from system memory to SIMCOP local memories requires two chained logical channels.

CAUTION

Software must ensure that only one trigger event source is selected at a given time for a logical channel; otherwise, unpredictable behavior may occur.

Typically, the following combinations can be used:

- Single channel triggered by software: Hardware synchronization and linking are disabled. Software writes the SIMCOP_DMA_CHAN_CTRL_i[2] SWTRIGGER bit to start the transfer of one 2D block. Software must not trigger the channel again before the CHANx_BLOCK_DONE_IRQ (where x = channel number) event is generated by the DMA.
- Channels chain-triggered by software: Multiple channels are linked together using the SIMCOP_DMA_CHAN_CTRL_i[16:12] LINKED bit field. Software triggers the first one in the chain and monitors the CHANx_BLOCK_DONE_IRQ (where x = channel number) event to know when the chain can be triggered again.
- Single channel triggered by hardware synchronization: Sensitivity on START pulses is activated through the SIMCOP_DMA_CHAN_CTRL_i[19:17] HWSTART bit field. DONE pulse generation is activated using the SIMCOP_DMA_CHAN_CTRL_i[22:20] HWSTOP bit field.
- Channels chain-triggered by hardware: Multiple channels are linked together using the SIMCOP_DMA_CHAN_CTRL_i[16:12] LINKED bit field. Sensitivity on START pulses is activated for the first channel in the chain through the SIMCOP_DMA_CHAN_CTRL_i[19:17] HWSTART bit field. DONE pulse generation for the last channel in the chain is activated using the SIMCOP_DMA_CHAN_CTRL_i[22:20] HWDONE bit field.

8.4.3.3.4.3 Logical Channel Data Transfer

Each logical channel can handle 4D transfers from system memory to SIMCOP memory and vice versa.

A frame is composed of SIMCOP_DMA_CHAN_FRAME_i[9:0] XCNT * SIMCOP_DMA_CHAN_FRAME_i[25:16] YCNT 2D blocks of data. A single 2D block of data is transferred each time a logical channel is in the RUNNING state.

The size of a 2D block is SIMCOP_DMA_CHAN_BLOCK_SIZE_i[13:4] XNUM * SIMCOP_DMA_CHAN_BLOCK_SIZE_i[28:16] YNUM words of 128 bits. The SIMCOP DMA can transfer only full 128-bit words.

2D blocks may overlap in system memory. This feature is typically used for source data fetches from system memory to handle filter dependencies. If this feature is not used, software must set:

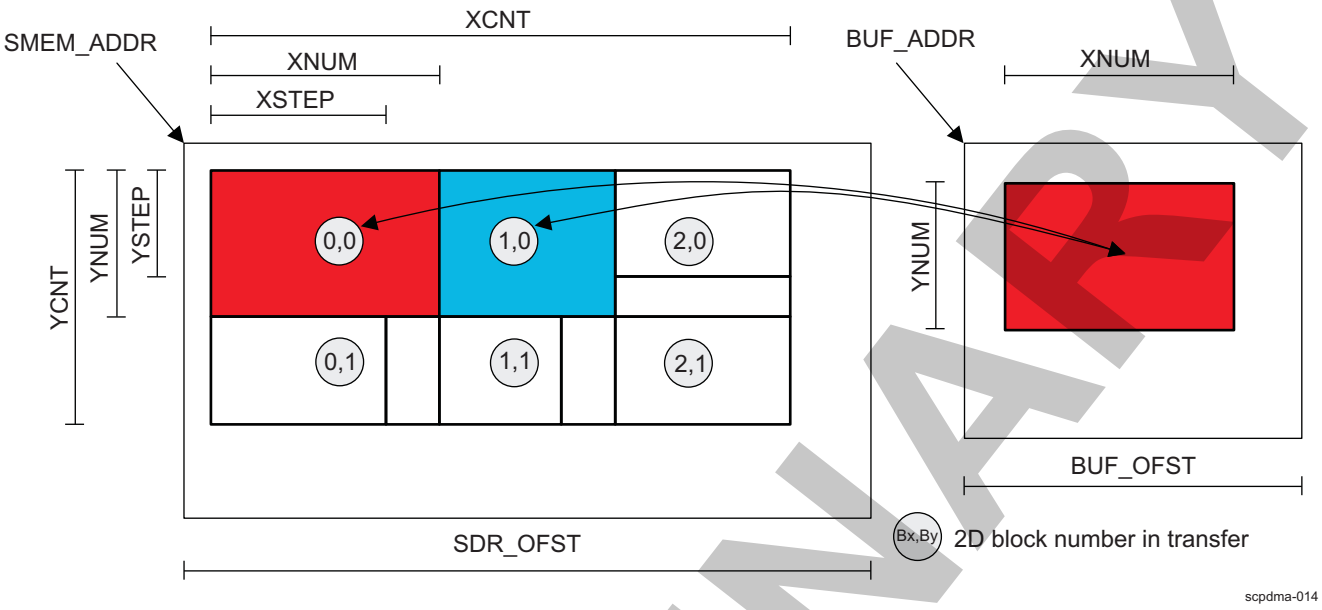
- SIMCOP_DMA_CHAN_BLOCK_SIZE_i[13:4] XNUM = SIMCOP_DMA_CHAN_BLOCK_STEP_i[14:4] XSTEP
- SIMCOP_DMA_CHAN_BLOCK_SIZE_i[28:16] YNUM = SIMCOP_DMA_CHAN_BLOCK_STEP_i[29:16] YSTEP

Figure 8-275 shows DMA addressing.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 8-275. DMA Addressing



The base position of 2D blocks in system memory is automatically computed by the SIMCOP DMA. The base address is computed using the following formula:

SMEM_BASE = SIMCOP_DMA_CHAN_SMEM_ADDR_i[31:4] ADDR +
Bx × SIMCOP_DMA_CHAN_BLOCK_STEP_i[14:4] XSTEP +
By × SIMCOP_DMA_CHAN_BLOCK_STEP_i[29:16] YSTEP ×
SIMCOP_DMA_CHAN_SMEM_OFST_i[19:4] OFST

All 2D blocks of a logical channel have the same location in SIMCOP local memories:

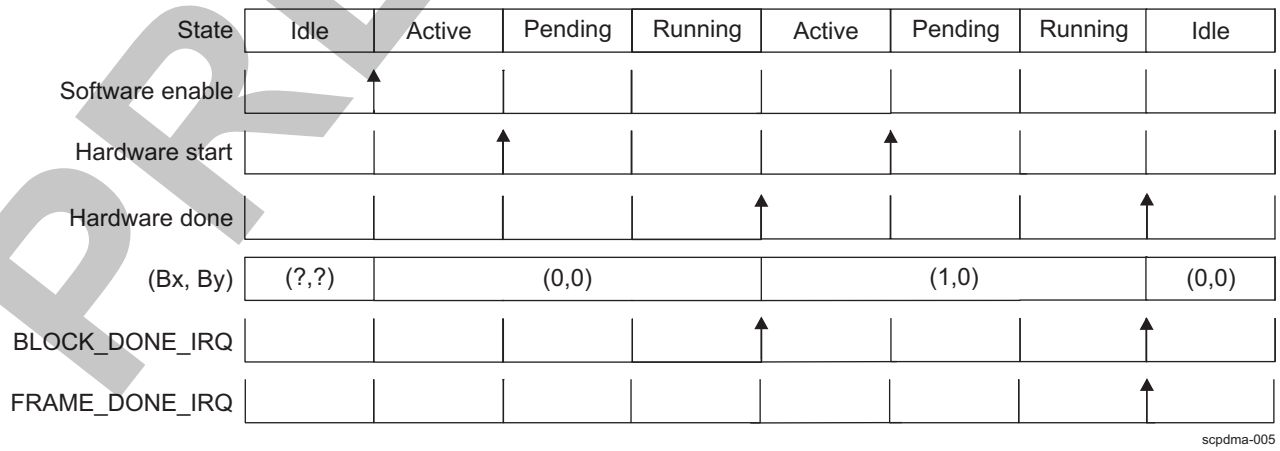
BUF_BASE = SIMCOP_DMA_CHAN_BUF_ADDR_i[23:4] ADDR

The same functionality can also be used to read or write sparse data from SDRAM. Typically, that is useful to split processing between two SIMCOP accelerators .

Software can poll the status of a channel using the SIMCOP_DMA_CHAN_CURRENT_BLOCK_i register. It holds the Bx, By values of the last-transferred 2D block. The Bx, By values are reset when a channel is enabled (set the SIMCOP_DMA_CHAN_CTRL_i[0] ENABLE bit) and they are updated when a channel enters the RUNNING state.

Figure 8-276 shows an example of a 2-block large transfer.

Figure 8-276. 2-Block Large Transfer Example



PRELIMINARY

8.4.3.3.5 Transaction Generation

Each transfer is decomposed into one or multiple transactions by the DMA engine. The firmware can define:

- Burst generation for regular or tiled accesses (SIMCOP_DMA_CHAN_CTRL_i[6] TILERMODE). Additional parameters must be defined for tiled accesses. See Section 8.4.3.3.5.2, *Block Bursts for Tiled Transfers*.
- The maximum burst size (SIMCOP_DMA_CTRL[1:0] MAX_BURST_SIZE). It must be aligned with the interconnect configuration.
- Use of posted or nonposted writes (SIMCOP_DMA_CTRL[3] POSTED_WRITES). It must be aligned with the interconnect configuration. Mainly, in a multichannel system memory, system bursts must be issued nonposted.

8.4.3.3.5.1 Incrementing Bursts for Regular Transfers

Lines of 2D blocks are processed sequentially. The following transaction process is used for a given line:

1. Perform a single nonaligned burst from the start address to the next SIMCOP_DMA_CTRL[1:0] MAX_BURST_SIZE boundary (or less if the transfer is smaller).
2. Perform "n" aligned bursts (n can be 0).
3. Perform a single nonaligned burst up to the end address (if needed).

A transaction is aligned when the start address modulo burst length is 0.

8.4.3.3.5.2 Block Bursts for Tiled Transfers

The line stride is configured using the SIMCOP_DMA_CHAN_SMEM_OFST_i[19:4] OFST bit field. The full register content is used for internal address computation. The SIMCOP_DMA_CHAN_SMEM_OFST_i[19:4] OFST bit field must be a multiple of the SIMCOP_DMA_CTRL[1:0] MAX_BURST_SIZE bit field.

The SIMCOP DMA has the following alignment constraints:

- SIMCOP_DMA_CHAN_SMEM_ADDR_i[31:4] ADDR is 128 bit-aligned.
- SIMCOP_DMA_CHAN_BLOCK_SIZE_i[13:4] XNUM is 128 bit-aligned.

Only the values in Table 8-1416 are allowed for the SIMCOP_DMA_CTRL[1:0] MAX_BURST_SIZE bit field. Other values lead to undefined behavior.

Table 8-1416. Allowed Max Burst Size

Minimum Burst Height	MAX_BURST_SIZE
2	2, 4, or 8 x 128 bits
4	4 or 8 x 128 bits

8.4.3.4 ISS SIMCOP DMA Basic Programming Model

8.4.3.4.1 Initialization of Surrounding Modules

To initialize the DMA, the surrounding modules must be initialized. Table 8-1417 lists these modules.

Table 8-1417. Initialization of Surrounding Modules

Module	Minimum Required Setting	Optional Settings
CLKC	Enable SIMCOP clock	
Buffers	Configure DMA access to image buffer	
SIMCOP CTRL		Configure SIMCOP CTRL to handle DMA interrupts

8.4.3.4.2 ISS SIMCOP DMA Channel Configuration and Hardware Synchronization

Software must fully configure a DMA channel before enabling it. It then configures channel linking and the used synchronization method.

The following example shows four logical channels chained with hardware synchronization used to copy YUV4:2:0-NV12 data from SIMCOP local memories to system memory, and then to copy YUV4:2:0-NV12 data from system memory to SIMCOP local memories.

YUV4:2:0-NV12 data is stored in two separate buffers in SDRAM. Therefore, two channels are used for the SIMCOP -> system copy, and two channels are used for the system -> SIMCOP copy.

In this example, the intent is to transfer a 2 x 2 array of 64 x 32 pixel blocks. It is assumed that input data is stored contiguously in system memory and that the output buffer size in system memory is 256 x 32 pixels. In SIMCOP local memories, data is contiguously stored starting at address 0

The following configuration is used:

- Channel i = 0, input Y buffer:
  - SIMCOP_DMA_CHAN_SMEM_ADDR_i[31:4] ADDR = Start address of Y input buffer
  - SIMCOP_DMA_CHAN_SMEM_OFST_i[19:4] OFST = 16 (= 256 bytes)
  - SIMCOP_DMA_CHAN_BUF_ADDR_i[23:4] ADDR = 0
  - SIMCOP_DMA_CHAN_BUF_OFST_i[23:4] OFST = 8 (= 128 bytes)
  - SIMCOP_DMA_CHAN_BLOCK_SIZE_i[13:4] XNUM = 4 (= 64 bytes)
  - SIMCOP_DMA_CHAN_BLOCK_SIZE_i[28:16] YNUM = 32
  - SIMCOP_DMA_CHAN_FRAME_i[9:0] XCNT = 2
  - SIMCOP_DMA_CHAN_FRAME_i[25:16] YCNT = 2
  - SIMCOP_DMA_CHAN_BLOCK_STEP_i[14:4] XSTEP = 4 (= 64 bytes)
  - SIMCOP_DMA_CHAN_BLOCK_STEP_i[29:16] YSTEP = 32
- Channel i = 1, input UV buffer:
  - SIMCOP_DMA_CHAN_SMEM_ADDR_i[31:4] ADDR = Start address of UV input buffer
  - SIMCOP_DMA_CHAN_SMEM_OFST_i[19:4] OFST = 16 (= 256 bytes)
  - SIMCOP_DMA_CHAN_BUF_ADDR_i[23:4] ADDR = 128 (2 KiB)
  - SIMCOP_DMA_CHAN_BUF_OFST_i[23:4] OFST = 8 (= 128 bytes)
  - SIMCOP_DMA_CHAN_BLOCK_SIZE_i[13:4] XNUM = 4 (= 64 bytes)
  - SIMCOP_DMA_CHAN_BLOCK_SIZE_i[28:16] YNUM = 16
  - SIMCOP_DMA_CHAN_FRAME_i[9:0] XCNT = 2
  - SIMCOP_DMA_CHAN_FRAME_i[25:16] YCNT = 2
  - SIMCOP_DMA_CHAN_BLOCK_STEP_i[14:4] XSTEP = 4 (= 64 bytes)
  - SIMCOP_DMA_CHAN_BLOCK_STEP_i[29:16] YSTEP = 16
- Channel i = 2, output Y buffer:

PRELIMINARY

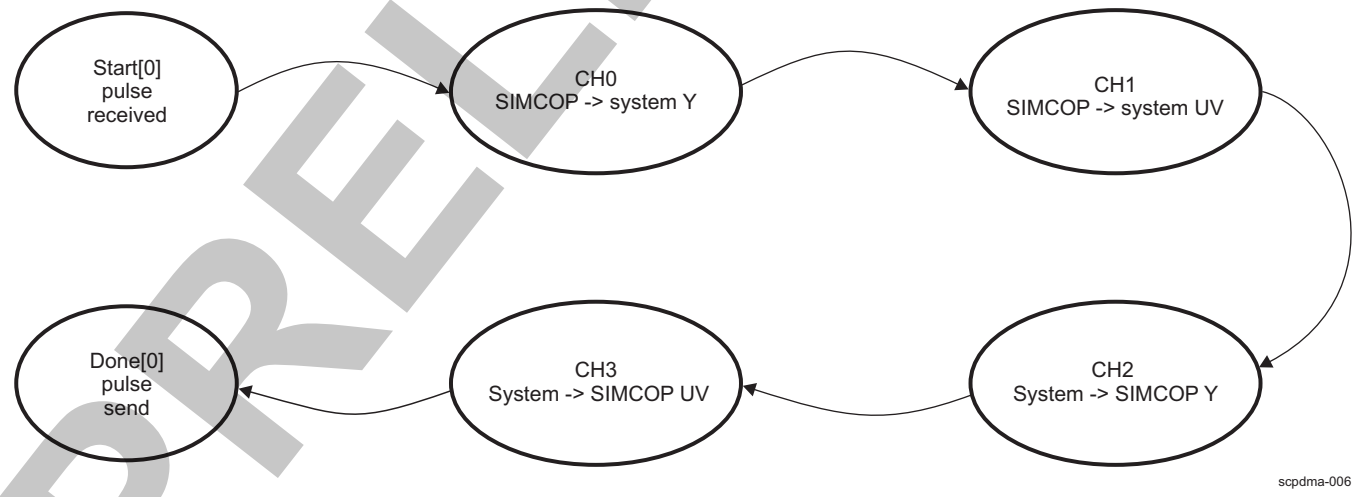
Copyright © 2013, Texas Instruments Incorporated

  - SIMCOP_DMA_CHAN_SMEM_ADDR_i[31:4] ADDR = Start address of Y output buffer
  - SIMCOP_DMA_CHAN_SMEM_OFST_i[19:4] OFST = 16 (= 256 bytes)
  - SIMCOP_DMA_CHAN_BUF_ADDR_i[23:4] ADDR = 0
  - SIMCOP_DMA_CHAN_BUF_OFST_i[23:4] OFST = 8 (= 128 bytes)
  - SIMCOP_DMA_CHAN_BLOCK_SIZE_i[13:4] XNUM = 4 (= 64 bytes)
  - SIMCOP_DMA_CHAN_BLOCK_SIZE_i[28:16] YNUM = 32
  - SIMCOP_DMA_CHAN_FRAME_i[9:0] XCNT = 2
  - SIMCOP_DMA_CHAN_FRAME_i[25:16] YCNT = 2
  - SIMCOP_DMA_CHAN_BLOCK_STEP_i[14:4] XSTEP = 4 (= 64 bytes)
  - SIMCOP_DMA_CHAN_BLOCK_STEP_i[29:16] YSTEP = 32
- Channel i = 3, output UV buffer
  - SIMCOP_DMA_CHAN_SMEM_ADDR_i[31:4] ADDR = Start address of UV output buffer
  - SIMCOP_DMA_CHAN_SMEM_OFST_i[19:4] OFST = 16 (= 256 bytes)
  - SIMCOP_DMA_CHAN_BUF_ADDR_i[23:4] ADDR = 128 (= 2 KiB)
  - SIMCOP_DMA_CHAN_BUF_OFST_i[23:4] OFST = 8 (= 128 bytes)
  - SIMCOP_DMA_CHAN_BLOCK_SIZE_i[13:4] XNUM = 4 (= 64 bytes)
  - SIMCOP_DMA_CHAN_BLOCK_SIZE_i[28:16] YNUM = 16
  - SIMCOP_DMA_CHAN_FRAME_i[9:0] XCNT = 2
  - SIMCOP_DMA_CHAN_FRAME_i[25:16] YCNT = 2
  - SIMCOP_DMA_CHAN_BLOCK_STEP_i[14:4] XSTEP = 4 (= 64 bytes)
  - SIMCOP_DMA_CHAN_BLOCK_STEP_i[29:16] YSTEP = 16

Figure 8-277 shows the channel linking chain used. All four channels are executed sequentially. Doing so prevents access collision in SIMCOP local memories or system memories. Channel 0 is started by a START[0] pulse from SIMCOP. When Channel 3 completes the last transfer, a pulse to DONE[0] is sent back to SIMCOP.

Figure 8-278 shows the temporal channel sequence.

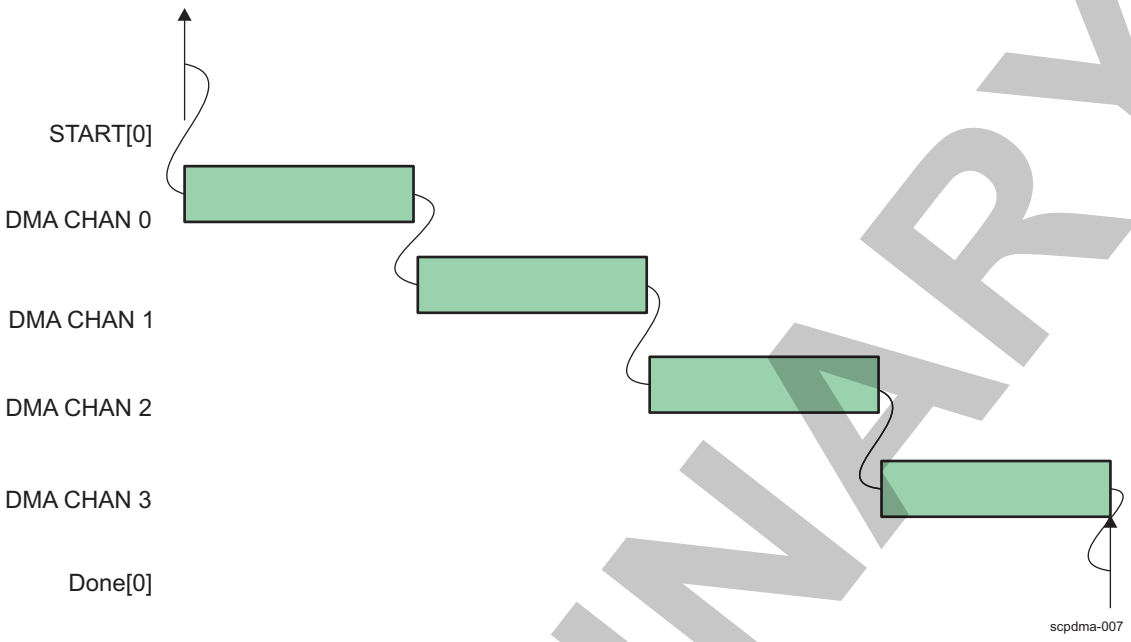
Figure 8-277. YUV4:2:0-NV12 Read/Write Chain



PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 8-278. Temporal Channel Sequence



The following configuration is used for each channel:

- Channel i = 0, input Y buffer, first in sequence:
  - SIMCOP_DMA_CHAN_CTRL_i[16:12] LINKED = 0x11 (= CHAN 1)
  - SIMCOP_DMA_CHAN_CTRL_i[19:17] HWSTART = 0x4 (= CHAN 0)
  - SIMCOP_DMA_CHAN_CTRL_i[5] DIR = 1 (= SIMCOP buffers -> system memory)
  - SIMCOP_DMA_CHAN_CTRL_i[0] ENABLE = 1
- Channel i = 1, input UV buffer, second in sequence:
  - SIMCOP_DMA_CHAN_CTRL_i[16:12] LINKED = 0x12 (= CHAN 2)
  - SIMCOP_DMA_CHAN_CTRL_i[5] DIR = 1 (= SIMCOP buffers -> system memory)
  - SIMCOP_DMA_CHAN_CTRL_i[0] ENABLE = 1
- Channel i = 2, output Y buffer, third in sequence:
  - SIMCOP_DMA_CHAN_CTRL_i[16:12] LINKED = 0x13 (= CHAN 3)
  - SIMCOP_DMA_CHAN_CTRL_i[5] DIR = 0 (= system memory -> SIMCOP buffers)
  - SIMCOP_DMA_CHAN_CTRL_i[0] ENABLE = 1
- Channel i = 3, output UV buffer, last in sequence:
  - SIMCOP_DMA_CHAN_CTRL_i[16:12] LINKED = CHAN 1
  - SIMCOP_DMA_CHAN_CTRL_i[22:20] HWSTOP = 0x4 (= CHAN 0)
  - SIMCOP_DMA_CHAN_CTRL_i[5] DIR = 0 (= system memory -> SIMCOP buffers)
  - SIMCOP_DMA_CHAN_CTRL_i[0] ENABLE = 1

Software can read the status of a logical channel at any time. However, logical channel configuration registers can be changed only when the channel is in the IDLE state.

Software can disable a logical channel by writing the SIMCOP_DMA_CHAN_CTRL_i[1] DISABLE bit. A channel is effectively disabled when SIMCOP_DMA_CHAN_CTRL_i[4:3] STATUS = IDLE. In case of linked channels, software must disable all channels in the chain and wait until all of them are back in the IDLE state before channels can be reprogrammed.

8.4.3.4.3 Software Synchronization

Software performs the following sequence:

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

1. Configures the channel
2. Enables the channel
3. Triggers the channel by writing the SIMCOP_DMA_CHAN_CTRL_i[2] SWTRIGGER bit
4. Waits for BLOCK_DONE_IRQ

Step 2 and Step 4 are repeated until all 2D blocks have been transferred.

Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BW_LIMITER																RESERVED								TAG_CNT				POSTED_WRITES	RESERVED	MAX_BURST_SIZE	

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
31:16	BW_LIMITER	SIMCOP DMA guarantees that there are at least BW_LIMITER functional clock cycles between two OCP requests. No IDLE cycles are inserted during an OCP transaction. This parameter could be used to reduce traffic generated by the SIMCOP DMA for non timing critical applications. Doing so leaves more BW for other system initiators. Default value corresponds to maximum performance.	RW	0x0000
15:8	RESERVED		R	0x00
7:4	TAG_CNT	Limits the outstanding transactions count. Only tags 0 - TAG_CNT will be used by SIMCOP DMA The maximum allowed value is $2^{(SIMCOCP_DMA_GNC.CONTEXT+2)-1}$	RW	0x3
3	POSTED_WRITES	Select write type. Setting depend on the used interconnect 0x0: Only non posted writes are generated 0x1: Only posted writes are generated	RW	0
2	RESERVED		R	0
1:0	MAX_BURST_SIZE	Defines the maximum burst length for INCR bursts. In case of 2D bursts, length x height is less or equal to this value. 0x0: Single requests only 0x1: less or equal to 2 0x2: less or equal to 4 0x3: less or equal to 8	RW	0x0

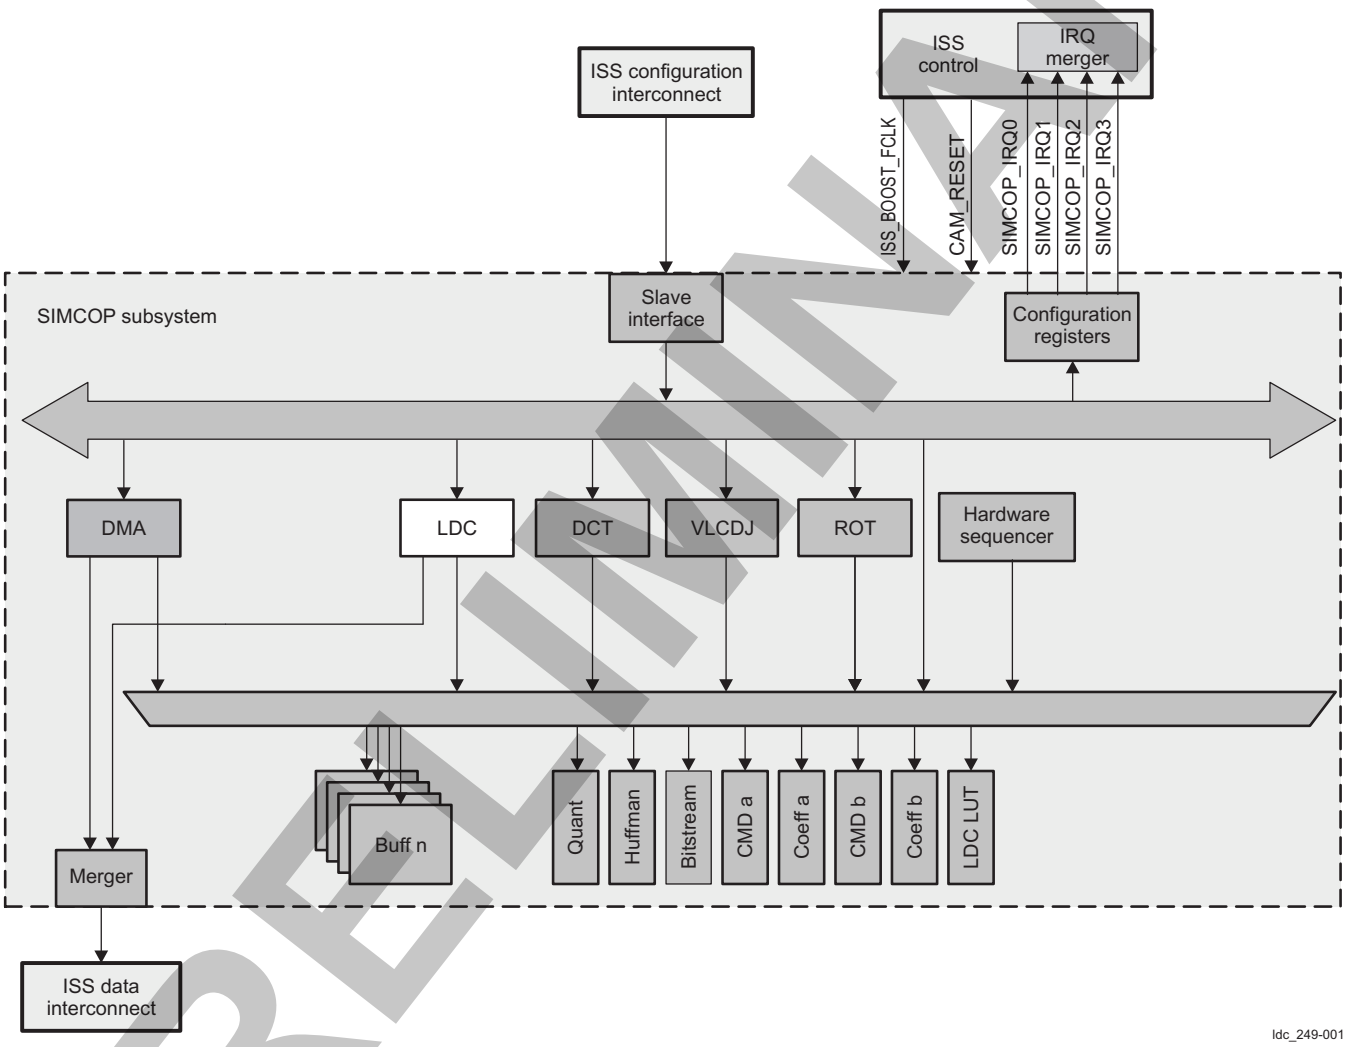
8.4.4 ISS SIMCOP LDC Module

This chapter describes the lens distortion correction (LDC) module in the still image coprocessor (SIMCOP) subsystem.

8.4.4.1 ISS SIMCOP LDC Overview

The lens distortion correction (LDC) module deals with lens geometric distortion issues, chromatic aberration, and affine transformation for camera images. Figure 8-279 is an overview of the LDC in the SIMCOP subsystem.

Figure 8-279. LDC in the SIMCOP Subsystem



For still image or video applications the LDC supports:

- Lens distortion correction:
  - YCbCr4:2:2/YCbCr4:2:0 data format input/output for post-image-pipe correction
  - Correct barrel distortion and pin-cushion distortion
  - Radius-to-magnification-factor table to accommodate various distortion functions through programming
  - Configurable center point and horizontal/vertical adjustment
  - One 256-entry lookup table for Y, Cb, and Cr
  - 8 bits for YCbCr

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

  - Bicubic interpolation for Y and bilinear interpolation for Cb/Cr
  - Bilinear interpolation mode for Y to offer faster processing
  - Up to 16,383 x 16,383 image dimension
  - Format restriction:
    - YCbCr4:2:2 format: Tile width must be a multiple of 16.
    - YCbCr4:2:0 format: Tile width must be a multiple of 32.
- Image warping, scaling, and rotation:
  - Affine transformation for image warping, scaling, and rotation
  - 8 bits for YCbCr
  - Bicubic interpolation for Y and bilinear interpolation for Cb/Cr
  - Bilinear interpolation mode for Y to offer double throughput
  - Format restriction:
    - YCbCr4:2:2 format: Tile width must be a multiple of 16.
    - YCbCr4:2:0 format: Tile width must be a multiple of 32.
- Chromatic aberration correction:
  - Supports Bayer data in unpacked 12-bit per pixel, 8-bit per pixel A-Law, 8-bit per pixel unpacked, and 12-bit per pixel packed formats
  - Radius-to-magnification-factor table to accommodate various distortion functions through programming
  - Configurable center point and horizontal/vertical adjustment
  - Red and blue distortion only. Green pixels are copied to output.
  - Independent 128-entry lookup tables for red and blue
  - Bilinear interpolation
  - Up to 16,383 x 16,383 image dimension
  - Format restriction:
    - Unpacked 12-bit format: Tile width must be a multiple of 16.
    - A-Law 8-bit format: Tile width must be a multiple of 32.
    - Unpacked 8-bit format: Tile width must be a multiple of 32.
    - Packed 12-bit format: Tile width must be a multiple of 64.

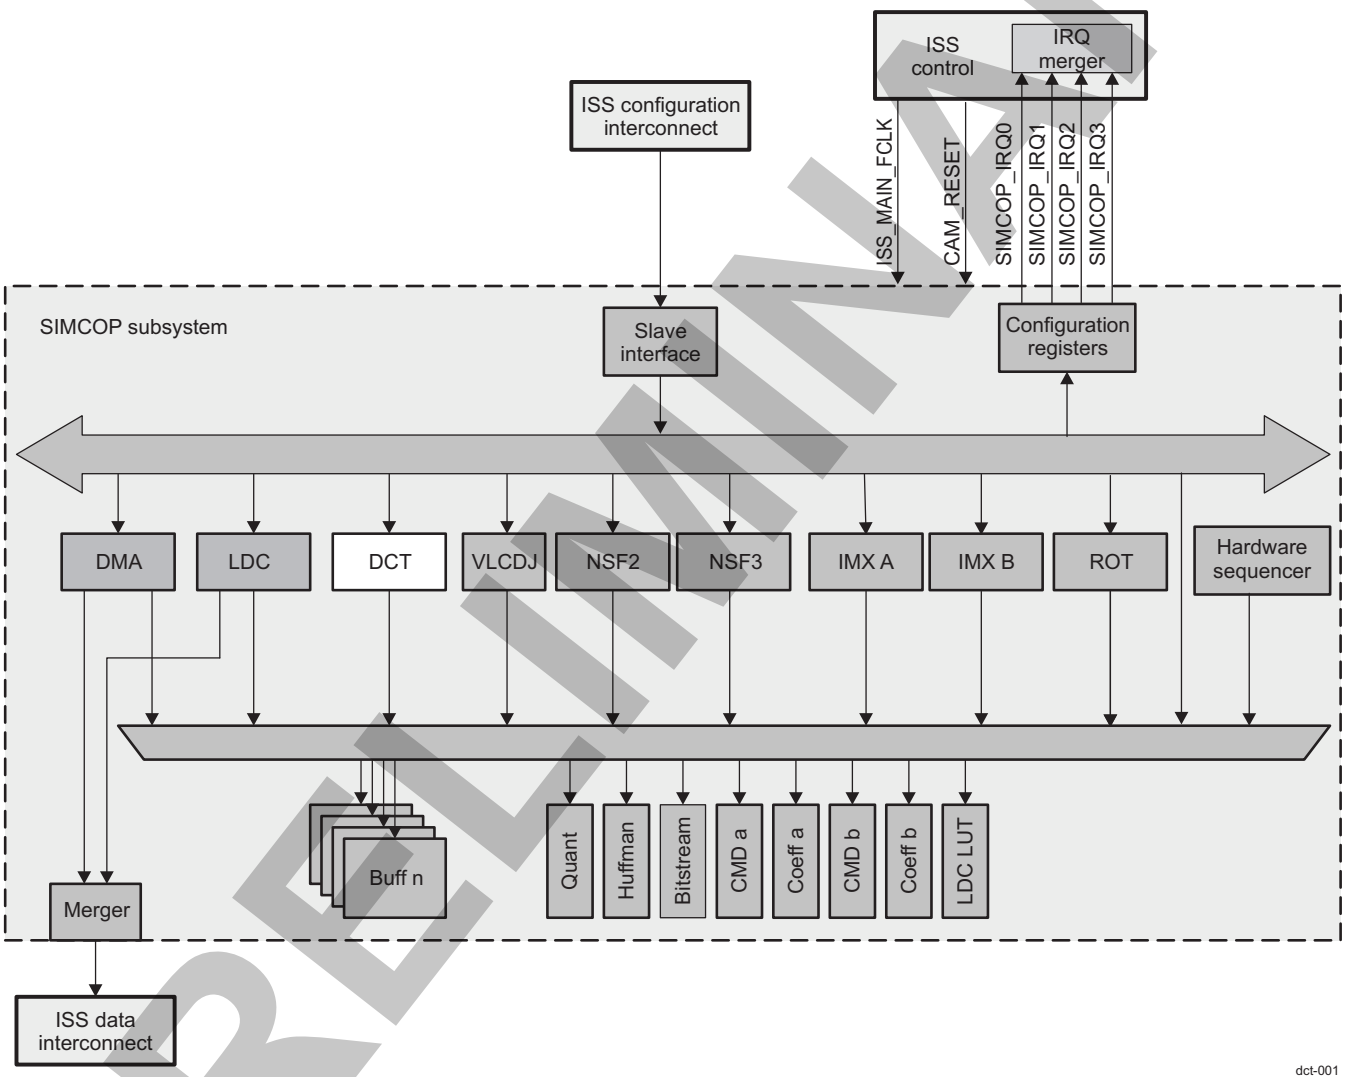
8.4.5 ISS SIMCOP Discrete Cosine Transform (DCT) Module

This section describes the discrete cosine transform (DCT) module in the still-image coprocessor (SIMCOP) subsystem.

8.4.5.1 ISS SIMCOP DCT Overview

The discrete cosine transform (DCT) module performs DCT and inverse DCT (IDCT) operations required for still-image coder/decoder (codec) applications. Figure 8-280 is an overview of the DCT in the still-image coprocessor (SIMCOP) subsystem.

Figure 8-280. DCT in the SIMCOP Subsystem



For still-image or video applications, the DCT supports:

- 8-bit data in the spatial domain (input to DCT or output of IDCT) with –128 offset on color components
- 16-bit data in the frequency domain
- Exact input/output (I/O) range:
  - DCT expected input range [0, 255], subtracting 128 offset before transform, output saturated to [–1024, 1023]
  - IDCT expected input range [–1280, 1079], adding 128 to inverse transform outcome and saturating to [0, 255]
  - IDCT input range is from DCT output range plus [–256, 256] worst-case quantization error

PRELIMINARY

- Configurable to process up to 32 microcontroller units (MCUs) at a time (21 MCUs for YUV4:2:0, and 32 MCUs for YUV4:2:2, because of memory size limitations
- The following formats are supported by the DCT:
  - 16 x 16-pixel block MCU for YUV4:2:0 format, spatial data storage follows NV12
  - 16 x 8-pixel block MCU for YUV4:2:2 format, spatial data storage follows UYVY
  - Sequential 8 x 8 block mode, other than YUV4:2:0 and YUV4:2:2, a color-neutral format to allow flexibility in color component configuration in MCU, processes up to 64 blocks per task
- JPEG baseline sequential is supported by sequential 8 x 8 block mode. Some post-processing to reorder data and color space conversion may be required.
- All frequency domain data are stored sequentially for each 8 x 8 block, 16 bits per data point.

8.4.5.2 ISS SIMCOP DCT Integration

The DCT is part of the SIMCOP subsystem in the imaging subsystem (ISS). Figure 8-281 shows the integration of the DCT in the SIMCOP subsystem.

Figure 8-281. DCT Engine Integration

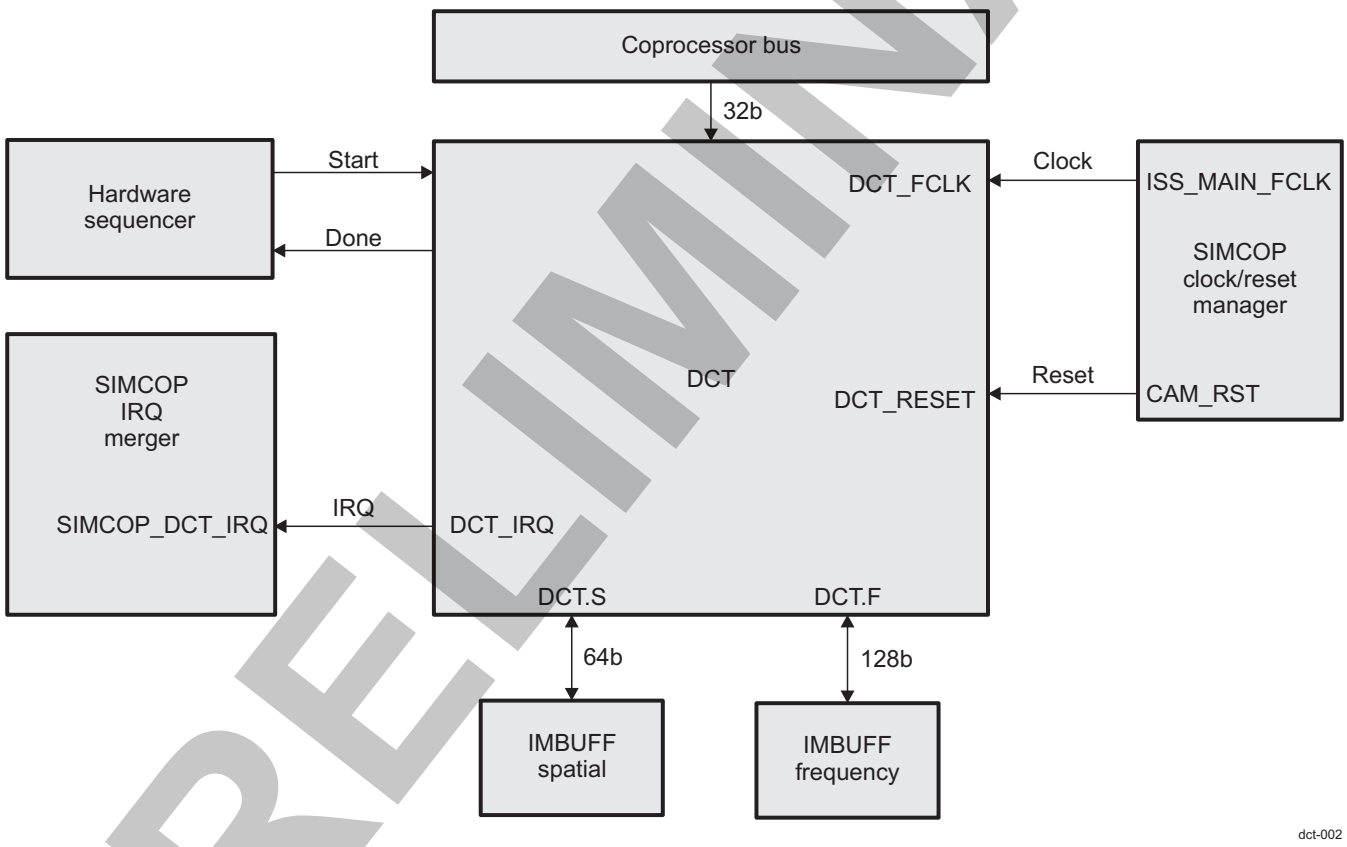

Table 8-1454 through Table 8-1456 list the integration attributes, clocks and resets, and hardware requests, respectively, for the DCT.

8.4.5.3 ISS SIMCOP DCT Functional Description

8.4.5.3.1 ISS SIMCOP DCT Block Diagram

The DCT implements 8 × 8 2-dimensional (2D) DCT and IDCT specified in JPEG image coding standards:

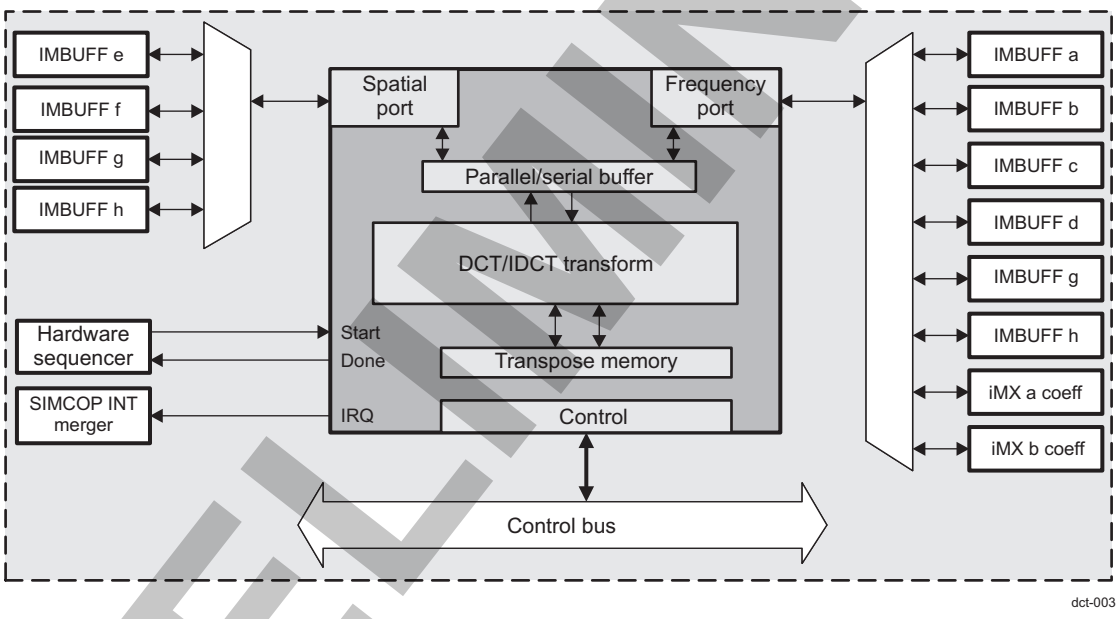
- In 4:2:0 mode, spatial domain data is organized in NV12 format. The frequency domain is organized as six blocks of 8 × 8.
- In 4:2:2 mode, spatial domain data is organized in UYVY format. The frequency domain is organized as four blocks of 8 × 8.
- In sequential 8 × 8 block mode, spatial and frequency domain data are organized as N blocks of 8 × 8 blocks.

NOTE:

- The spatial domain is the DCT input and IDCT output.
- The frequency domain is the DCT output and IDCT input.

Figure 8-282 is a block diagram of the DCT.

Figure 8-282. DCT Block Diagram



8.4.5.3.2 ISS SIMCOP DCT Power Management

Table 8-1457 describes the power-management features available for the DCT.

Table 8-1458. Events

Event Flag	Event Mask	Map to	Description
N/A	DCT_CFG[3] INTEN	DCT_IRQ	End of processing

8.4.5.3.4 Control and Status

The DCT is controlled through the control registers accessed through the coprocessor bus by an external initiator. Before starting the DCT, the buffer memory must be configured for DCT access and initialized, and the control register must be set (for more information about DCT/IDCT processing, see Section 8.4.5.3.4.1, *DCT Configuration*).

The DCT_CFG[4] TRIG_SRC bit is used to select the DCT start source:

- If TRIG_SRC = 0, the DCT is started through the DCT_CTRL[0] EN bit.
- If TRIG_SRC = 1, the DCT is started by a hardware-start signal generated by the SIMCOP hardware sequencer.

When the DCT is configured for one trigger, the other trigger has no effect on the DCT.

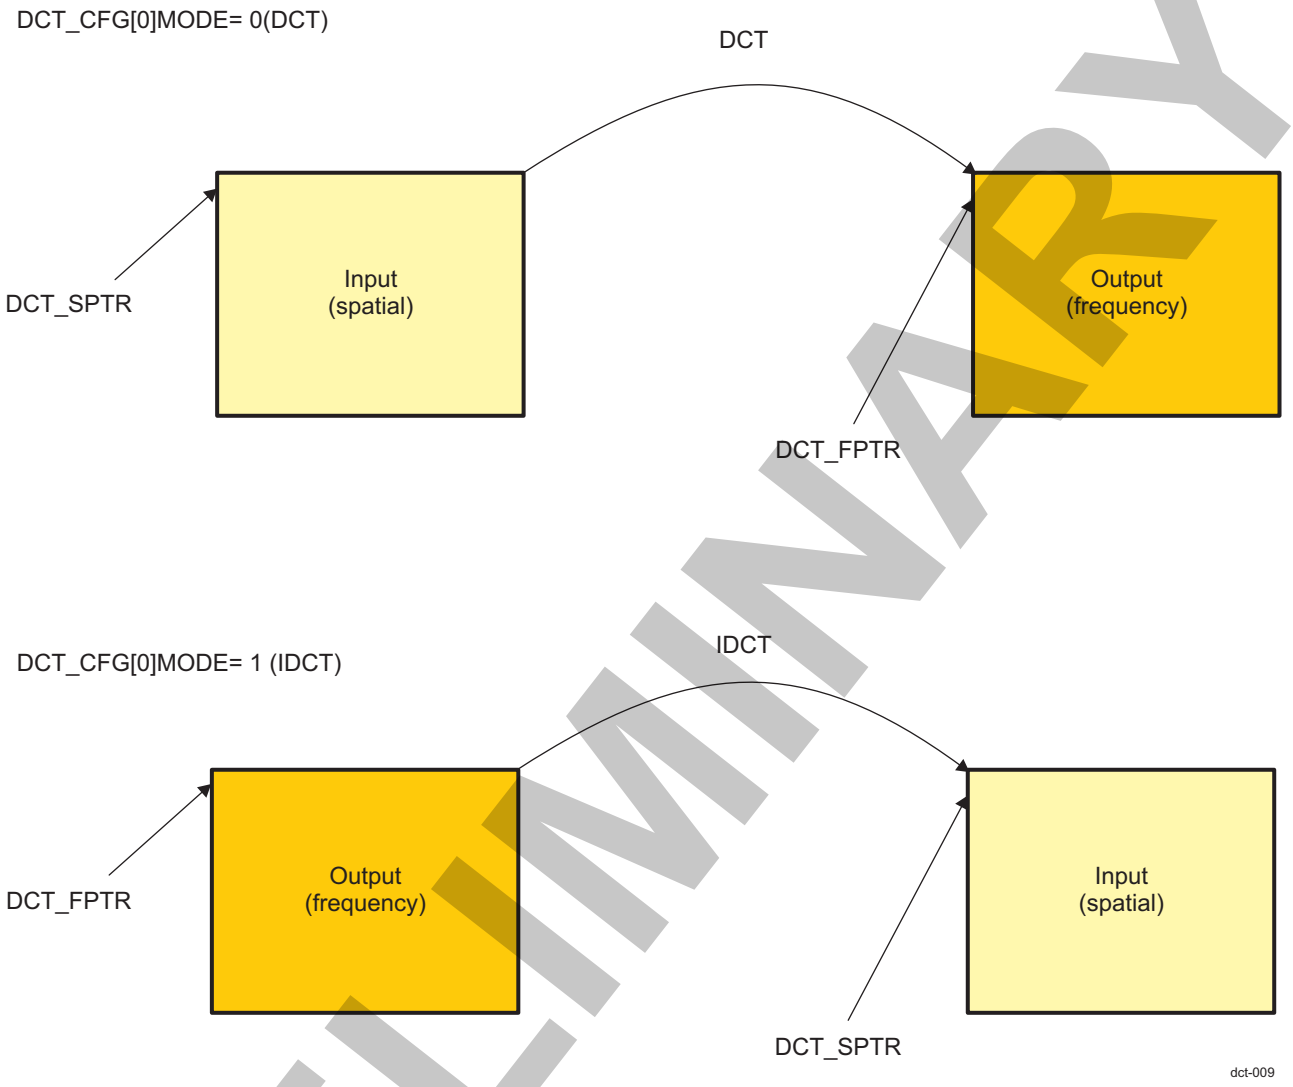
An external initiator can read the state of the DCT (running or not running) by reading the DCT_CTRL[15] BUSY bit. When the BUSY bit goes back to 0, processing is complete (TRIG_SRC = 0 or 1).

Before starting the DCT, the DCT_SPTR and DCT_FPTR registers must be configured with spatial and frequency addresses. Figure 8-283 shows the use of spatial and frequency addresses.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 8-283. DCT I/O Address Configuration



An interrupt can be generated when DCT operation completes (the configured number of MCUs for YUV4:2:0/4:2:2 mode, or the number of blocks for sequential block mode). To enable interrupt generation, set the DCT_CFG[3] INTEN bit to 1.

When the DCT_CFG[3] INTEN bit is set to 0, no interrupt generation is performed.

8.4.5.3.4.1 DCT Configuration

The following features can be configured in the DCT register:

- DCT module operation: The DCT_CFG[0] MODE bit configures the processing:
  - MODE = 0: DCT processing
  - MODE = 1: IDCT processing
- Number of MCUs to process: The number of MCUs to process –1 is configured in the DCT_CFG[13:8] NMCUS bit field:
  - YUV4:2:0 maximum MCUs = 21 (memory limitation, 126 blocks)
  - YUV4:2:2 maximum MCUs = 32 (128 blocks)
  - Sequential maximum MCUs = 64 (64 blocks)

PRELIMINARY

8.4.5.3.5 Data Format

The DCT reads and writes data from and to image buffers. I/O format can be configured in the DCT_CFG[2:1] FMT bit field. The following formats can be configured:

- YUV4:2:0
- YUV4:2:2
- Sequential

8.4.5.3.5.1 YUV4:2:0 Format

In JPEG YUV4:2:0 format, each MCU is 16 × 16 pixels, and has 16 × 16 Y data points, 8 × 8 U data points, and 8 × 8 V data points. Each square array of 8 × 8 data points is called a block. Thus, an MCU with a YUV4:2:0 format has four Y blocks, one U block, and one V block.

This module follows the NV12 data storage format for YUV4:2:0 spatial data. For YUV4:2:0 format:

- line_offset_in_bytes = (DCT_CFG[13:8] NMCUS + 1) × 16
- starting_addr_uv = DCT_SPTR + (DCT_CFG[13:8] NMCUS + 1) × 256

Figure 8-284 shows the organization of the data for two MCUs in the spatial domain, when the DCT is configured to process two MCUs. To select the YUV4:2:0 format, write 0 x 0 in the DCT_CFG[2:1] FMT bit field. YUV4:2:0 processes six blocks (four Y, one U, and one V) during each MCU DCT processing.

Figure 8-284. YUV4:2:0 Format Data Order

Byte offset	0	1	2	3	...	15	16	17	...	31
0	Y(0,0)	Y(1,0)	Y(2,0)	Y(3,0)	...	Y(15,0)	Y(16,0)	Y(17,0)	...	Y(31,0)
32	Y(0,1)	Y(1,1)	Y(2,1)	Y(3,1)	...	Y(15,1)	Y(16,1)	Y(17,1)	...	Y(31,1)
64	Y(0,2)	Y(1,2)	Y(2,2)	Y(3,2)	...	Y(15,2)	Y(16,2)	Y(17,2)	...	Y(31,2)
	:									
480	Y(0,15)	Y(1,15)	Y(2,15)	Y(3,15)	...	Y(15,15)	Y(16,15)	Y(17,15)	...	Y(31,15)
512	U(0,0)	V(0,0)	U(2,0)	V(2,0)	...	V(14,0)	U(16,0)	V(16,0)	...	V(30,0)
544	U(0,2)	V(0,2)	U(2,2)	V(2,2)	...	V(14,2)	U(16,2)	V(16,2)	...	V(30,2)
	:									
736	U(0,14)	V(0,14)	U(2,14)	V(2,14)	...	V(14,14)	U(16,14)	V(16,14)	...	V(30,14)

dct-005

Each YUV4:2:0 has four Y blocks, one U block, and one V block. For the first MCU in Figure 8-284, the blocks are:

- Y_Block 0:
  - Y(0, 0), Y(1, 0), ..., Y(7, 0)
  - Y(0, 1), Y(1, 1), ..., Y(7, 1)
  - ....
  - Y(0, 7), Y(1, 7), ..., Y(7, 7)
- Y_Block 1:
  - Y(8, 0), Y(9, 0), ..., Y(15, 0)
  - Y(8, 1), Y(9, 1), ..., Y(15, 1)
  - ....
  - Y(8, 7), Y(9, 7), ..., Y(15, 7)
- Y_Block 2:
  - Y(0, 8), Y(1, 8), ..., Y(7, 8)
  - Y(0, 9), Y(1, 9), ..., Y(7, 9)
  - ....
  - Y(0, 15), Y(1, 15), ..., Y(7, 15)
- Y_Block 3:
  - Y(8, 8), Y(9, 8), ..., Y(15, 8)

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

  - Y(8, 9), Y(9, 9), ..., Y(15, 9)
  - ....
  - Y(8, 15), Y(9, 15), ..., Y(15, 15)
- U_Block:
  - U(0, 0), U(2, 0), ..., U(14, 0)
  - U(0, 2), U(2, 2), ..., U(14, 2)
  - ....
  - U(0, 14), U(2, 14), ..., U(14, 14)
- V_Block:
  - V(0, 0), V(2, 0), ..., V(14, 0)
  - V(0, 2), V(2, 2), ..., V(14, 2)
  - ....
  - V(0, 14), V(2, 14), ..., V(14, 14)

8.4.5.3.5.2 YUV4:2:2 Format

In JPEG YUV4:2:2 format, each MCU is 16 x 8 pixels and has 16 x 8 Y data points, 8 x 8 U data points, and 8 x 8 V data points. Thus, an MCU with a 4:2:2 format has two Y blocks, one U block, and one V block.

This module follows the UYVY data storage format for YUV4:2:2 spatial data. For YUV4:2:2 format:

line_offset_in_bytes = (DCT_CFG[13:8] NMCUS + 1) × 16

starting_addr_uv=DCT_SPTR + (DCT_CFG[13:8] NMCUS+1) * 256

Figure 8-285 shows the organization of the data for two MCUs in the spatial domain, when the DCT is configured to process two MCUs. To select the YUV4:2:2 format, write 0 x 1 in the DCT_CFG[2:1] FMT bit field. YUV4:2:2 processes four blocks (two Y, one U, and one V) during each MCU DCT processing.

Figure 8-285. YUV4:2:2 Format Data Order

Byte Offset																
	0	1	2	3	4	5	6	7	...	31	32	33	34	35	...	63
0	U(0,0)	Y(0,0)	V(0,0)	Y(1,0)	U(2,0)	Y(2,0)	V(2,0)	Y(3,0)	...	Y(15,0)	U(16,0)	Y(16,0)	V(16,0)	Y(17,0)	...	Y(31,0)
64	U(0,1)	Y(0,1)	V(0,1)	Y(1,1)	U(2,1)	Y(2,1)	V(2,1)	Y(3,1)	...	Y(15,1)	U(16,1)	Y(16,1)	V(16,1)	Y(17,1)	...	Y(31,1)
128	U(0,2)	Y(0,2)	V(0,2)	Y(1,2)	U(2,2)	Y(2,2)	V(2,2)	Y(3,2)	...	Y(15,2)	U(16,2)	Y(16,2)	V(16,2)	Y(17,2)	...	Y(31,2)
	:															
448	U(0,7)	Y(0,7)	V(0,7)	Y(1,7)	U(2,7)	Y(2,7)	V(2,7)	Y(3,7)	...	Y(15,7)	U(16,7)	Y(16,7)	V(16,7)	Y(17,7)	...	Y(31,7)

dct-011

Each YUV4:2:2 has two Y blocks, one U block, and one V block. The four blocks of the first MCU are:

- Y_Block 0:
  - Y(0, 0), Y(1, 0), ..., Y(7, 0)
  - Y(0, 1), Y(1, 1), ..., Y(7, 1)
  - ....
  - Y(0, 7), Y(1, 7), ..., Y(7, 7)
- Y_Block 1:
  - Y(8, 0), Y(9, 0), ..., Y(15, 0)
  - Y(8, 1), Y(9, 1), ..., Y(15, 1)
  - ....
  - Y(8, 7), Y(9, 7), ..., Y(15, 7)

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

8.4.5.3.5.3 Sequential Block Format

The sequential block format supports any color format other than YUV4:2:0 or YUV4:2:2. There is no notion of colors, and each 8 x 8 block is ordered sequentially. The DCT can be configured to process N blocks (versus N MCUs for YUV4:2:0 and YUV4:2:2, N is up to 64). In this format:

- Block i =
  - X(8*i, 0), X(8*i+1, 0), ..., X(8*i+7, 0)
  - X(8*i, 1), X(8*i+1, 1), ..., X(8*i+7, 1)
  - ....
  - X(8*i, 7), X(8*i+1, 7), ..., X(8*i+7, 7)

To select sequential block format, write 0 x 2 in the DCT_CFG[2:1] FMT bit field.

8.4.5.4 ISS SIMCOP DCT Basic Programming Model

8.4.5.4.1 Initialization of Surrounding Modules

To initialize the DCT, the surrounding modules must be initialized. Table 8-1459 lists these modules.

Table 8-1459. Initialization of Surrounding Modules

Module	Minimum Required Setting	Optional Settings
CLKC	Enable the SIMCOP clock.	
Buffers	Configure DCT access to the image buffer.	
SIMCOP CTRL		Configure SIMCOP CTRL to handle DCT interrupts.

8.4.5.4.2 Using the DCT for DCT Processing

To configure the DCT for DCT processing, software must follow the procedure listed in Table 8-1460.

Table 8-1460. DCT Processing Procedure

Step	Register/Bit Field	Value
Prepare data in buffer memory.	SIMCOP buffers	
Switch buffer access to the DCT.	SIMCOP buffers	
Configure the start of the DCT input address (address must be in the memory buffer).	DCT_SPTR[12:5] ADDR	Start address (spatial domain)
Configure the start of the DCT output address (address must be in the memory buffer).	DCT_FPTR[13:4] ADDR	Start address (frequency domain)
Set the DCT_CFG register.	DCT_CFG[0] MODE	0 (DCT mode)
	DCT_CFG[2:1] FMT	Depends on data format
	DCT_CFG[3] INTEN	0: No interrupt 1: Interrupt at end of processing
	DCT_CFG[4] TRIG_SRC	1: Start controlled by hardware signal 0: Start controlled by a register
	DCT_CFG[13:8] NMCUS	Number of MCUs to process
IF: DCT_CFG[4] TRIG_SRC = 0		
Start DCT through the register.	DCT_CTRL[0] EN	1
ELSE		
Start the DCT using the hardware sequencer.	SIMCOP hardware sequencer	
ENDIF		

The DCT is now processing the blocks. To detect the end of DCT processing:

- If DCT_CFG[3] INTEN = 1, wait for the interrupt signal.
- If DCT_CFG[3] INTEN = 0, the processor must poll the DCT_CTRL[15] BUSY bit. When the BUSY bit is 0, processing is complete.

When DCT processing completes, the frequency output result is stored in the memory buffer at the address given by the DCT_FPTR[13:4] ADDR bit field.

8.4.5.4.3 Using the DCT for IDCT Processing

To configure the DCT for IDCT processing, software must follow the procedure listed in Table 8-1461.

Table 8-1461. IDCT Processing Procedure

Step	Register/Bit Field	Value
Prepare data in buffer memory.	SIMCOP buffers	
Switch buffer access to the DCT.	SIMCOP buffers	

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 8-1461. IDCT Processing Procedure (continued)

Step	Register/Bit Field	Value
Configure the start of the DCT output address (address must be in the memory buffer).	DCT_SPTR[12:5] ADDR	Start address (spatial domain)
Configure the start of the DCT input address (address must be in the memory buffer).	DCT_FPTR[13:4] ADDR	Start address (frequency domain)
Set the DCT_CFG register.	DCT_CFG[0] MODE	1 (IDCT mode)
	DCT_CFG[2:1] FMT	Depends on data format
	DCT_CFG[3] INTEN	0: No interrupt 1: Interrupt at end of processing
	DCT_CFG[4] TRIG_SRC	1: Start controlled by a hardware signal 0: Start controlled by a register
	DCT_CFG[13:8] NMCUS	Number of MCUs to process
IF: DCT_CFG[4] TRIG_SRC = 0		
Start the DCT through a register.	DCT_CTRL[0] EN	1
ELSE		
Start the DCT using hardware sequencer.	SIMCOP hardware sequencer	
ENDIF		

The DCT is now processing the blocks. To detect the end of DCT processing:

- If DCT_CFG[3] INTEN = 1, wait for the interrupt signal.
- If DCT_CFG[3] INTEN = 0, the processor must poll the DCT_CTRL[15] BUSY bit. When the BUSY bit is 0, processing is complete.

When IDCT processing completes, the spatial output result is stored in the memory buffer at the address given by the DCT_SPTR[12:5] ADDR bit field.

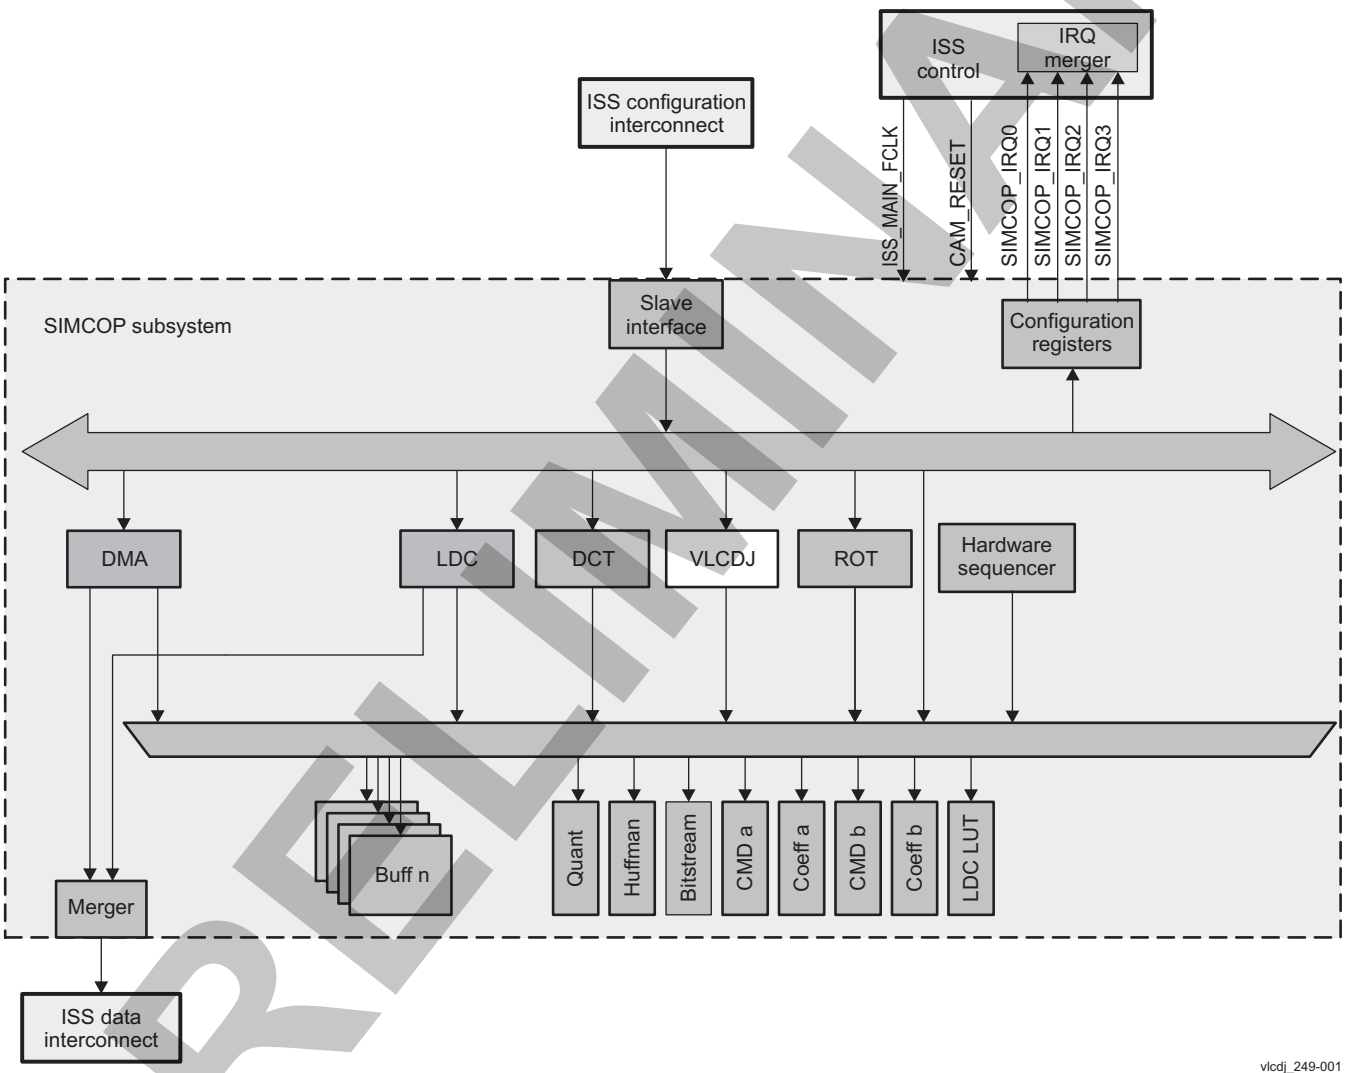
8.4.6 ISS SIMCOP Variable Length Coder/Decoder for JPEG (VLCDJ) Module

This section describes the variable-length coder/decoder for JPEG (VLCDJ) module in the still-image coprocessor (SIMCOP) subsystem.

8.4.6.1 ISS SIMCOP VLCDJ Overview

The variable-length coder/decoder for JPEG (VLCDJ) module handles quantization (Q) and variable-length coding (VLC) in JPEG encoding, and variable-length decoding (VLD) and inverse quantization (IQ) in JPEG decoding. These operations are required for JPEG image compression and decompression. Figure 8-286 is an overview of the VLCDJ in the still-image coprocessor (SIMCOP) subsystem.

Figure 8-286. VLCDJ in the SIMCOP Subsystem



The VLCDJ supports the following operations:

- Q and VLC for JPEG encoding
- VLD and IQ for JPEG decoding
- Data formats:
  - YUV4:2:0 format in 16 × 16-pixel microcontroller unit (MCU)
  - YUV4:2:2 format in 16 × 8-pixel MCU
  - Sequential block mode to support arbitrary color component configuration within JPEG baseline sequential (software intervention required to context-switch among color components)

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- Configurable for number of MCUs per initiation (up to 21 MCUs for YUV4:2:0, 32 MCUs for YUV4:2:2, 64 8 × 8 blocks for sequential block mode)
- Discrete cosine transform (DCT) coefficients are stored sequentially for each 8 × 8 block, 16 bits per data point
- Stall processing for interface with bitstream data overrun/underrun protection
- Insertion of restart markers during encoding (YUV4:2:0, YUV4:2:2, sequential block modes)
- Record of restart marker locations during encoding (YUV4:2:0, YUV4:2:2 only)
- Processing of restart markers on the MCU boundary during decoding, reset of direct coefficient (DC) predictors as required by the JPEG standard (YUV4:2:0, YUV4:2:2, sequential block modes)

8.4.6.2 ISS SIMCOP VLCDJ Integration

The VLCDJ is part of the SIMCOP subsystem in the imaging subsystem (ISS). Figure 8-287 shows the integration of the VLCDJ in the SIMCOP subsystem.

Figure 8-287. VLCDJ Engine Integration

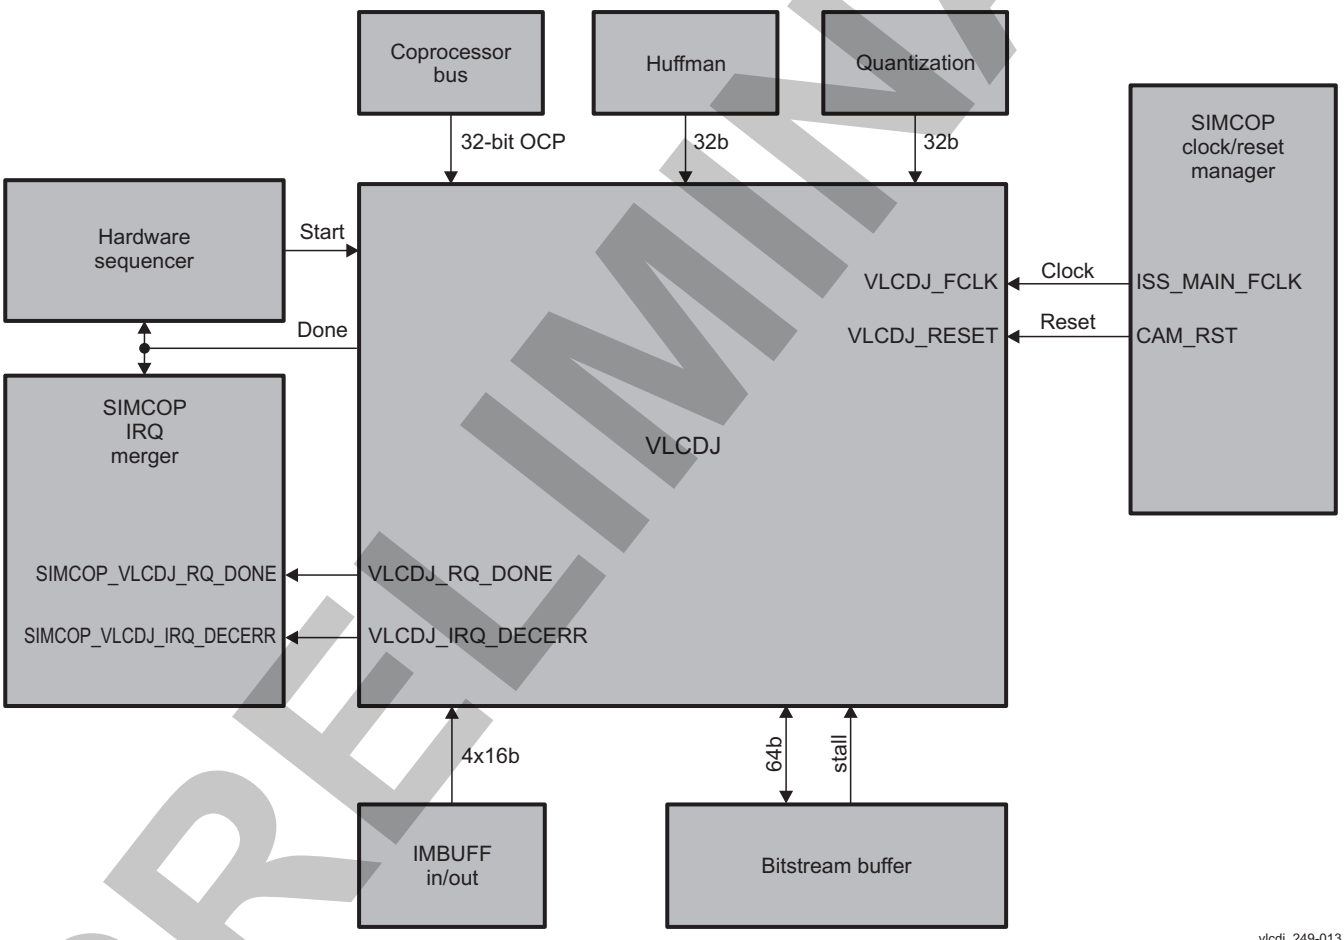


Table 8-1474 through Table 8-1476 list the integration attributes, clocks and resets, and hardware requests, respectively, for the VLCDJ.

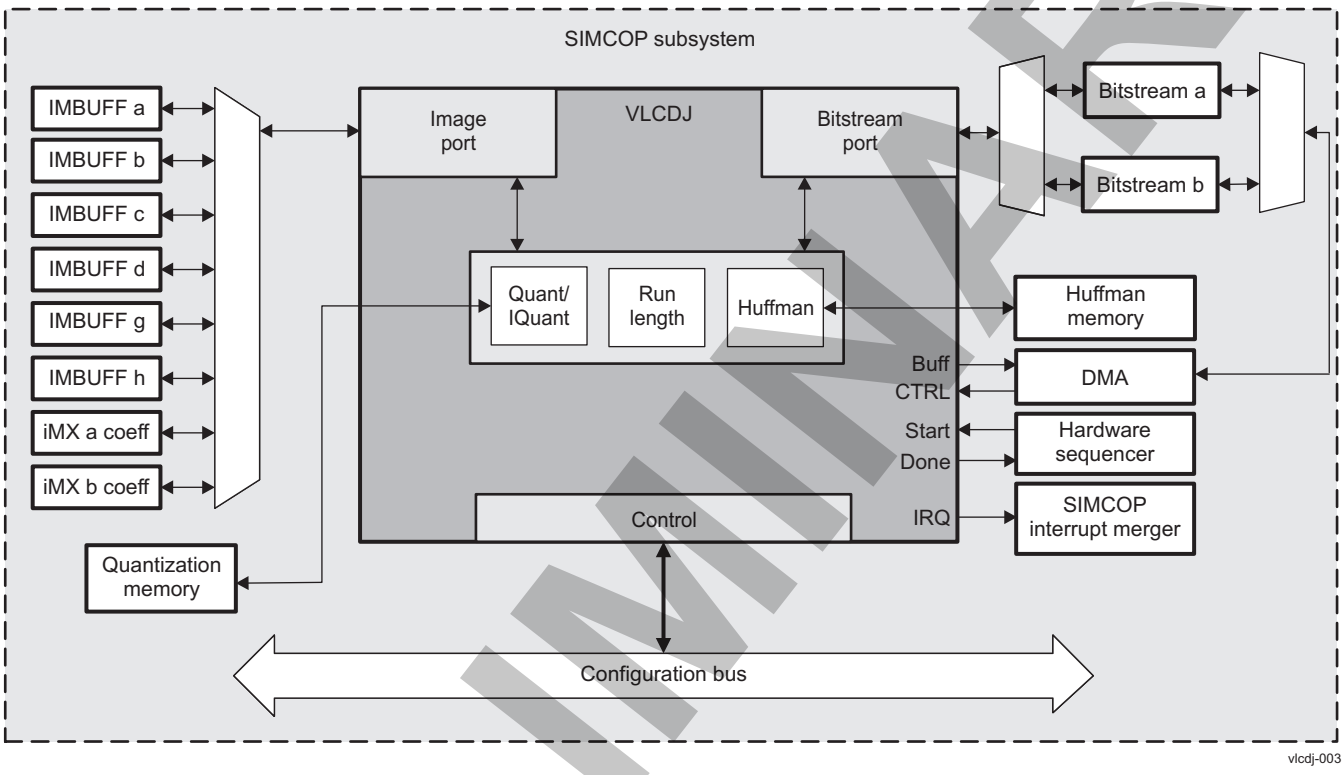
8.4.6.3 ISS SIMCOP VLCDJ Functional Description

8.4.6.3.1 ISS SIMCOP VLCDJ Block Diagram

The VLCDJ implements quantization, run-length encode, and Huffman encode stages of JPEG compression, and Huffman decode, run-length expansion, and dequantization stages of JPEG decompression. Figure 8-288 is a block diagram of the VLCDJ with connected memories and modules.

Figure 8-288. VLCDJ Block Diagram



8.4.6.3.2 ISS SIMCOP VLCDJ Power Management

The VLCDJ uses clock autogating to conserve power. When any substantial subblocks are not in use, the corresponding clock trees are gated off. Table 8-1477 describes the power-management feature available for the VLCDJ.

Table 8-1477. Local Power-Management Feature

Feature	Registers	Description
Clock autogating	VLCDJ_CTRL[3] AUTOGATING	Free-running or autogating modes are available.

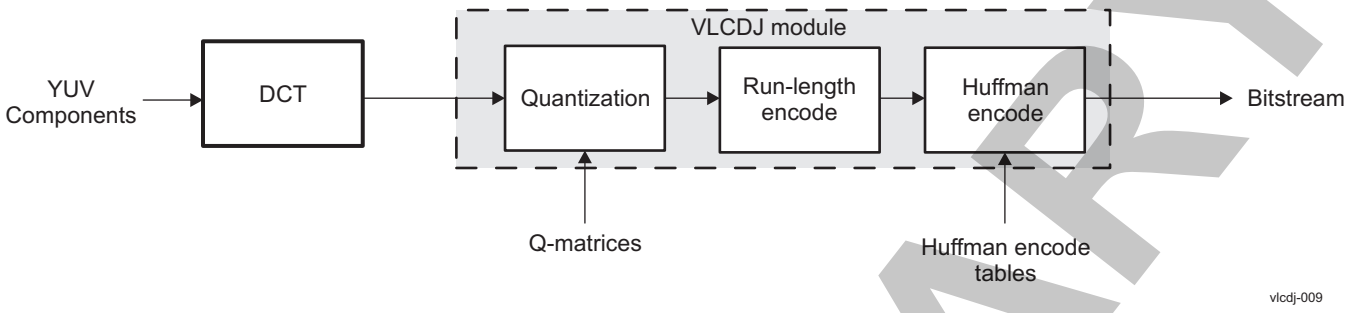
8.4.6.3.4 ISS SIMCOP VLCDJ in JPEG Encoding Flow

Figure 8-289 shows the JPEG compression or encoding flow.

Figure 8-289. JPEG Encoding Flow



The DCT coefficients are quantized by dividing each data point with a quantizer. The quantizers form an 8 × 8 matrix for Luma Y, and another 8 × 8 matrix for U and V, and the matrices are fixed in each image. The quantizer matrices can vary between images, and are sometimes fine-tuned in a multiple-pass process to regulate the compressed JPEG file size.

For quantization, VLCDJ reads a reciprocal of the quantizer values (16 bits per entry carrying 2^{15}/quant) so that hardware performs multiplications rather than divisions. The result is rounded to the nearest integer.

After quantization, the DC terms (the first term in each 8 × 8 block of DCT coefficients) are differentially coded within each color. Thus, three predictors are used for the common formats.

Next, the coefficients are scanned in a zigzag order (the same order for all colors) to form DC term + zero-run and nonzero level pairs for the alternative coefficient (AC) terms. The run-level pairs are then coded with a Huffman table.

The DC level is first categorized into size groups, basically the number of bits that represents the absolute value of the level. This size is translated to a bit segment using the Huffman table. Then, additional bits are appended to represent the exact DC level.

For AC run-level pairs, the process is similar. Each AC level is first categorized into size groups, basically the number of bits that represents the absolute value of the level. Then the size and the run are combined and translated to a bit segment using the Huffman table. Then, additional bits are appended to represent the exact AC level.

The number of additional bits to encode after the Huffman-coded segment, for DC or AC level, equals the size value. For example, coefficient values –3, –2, and 3 are of size 2, because 2 bits are required to represent the absolute values 2 and 3. There are four coefficient values in the size –2 category, so 2 additional bits are required to uniquely identify each value.

Some special symbols go with the AC run/size pairs. The ZRL symbol represents a run of 15 zeros, and is used to code unusually long zero runs. The EOB symbol represents end of block, meaning that there are only 0 AC coefficients at the end.

In the bitstream management level, after each byte of 0xFF, a byte of 0 is inserted to prevent the decoder from detecting special markers in the bitstream.

Because the VLCDJ handles multiple MCUs and allows restart marker insertion in MCU boundaries inside a task, the inserted flags are flagged to prevent the insertion of a 0 byte after 0xFF.

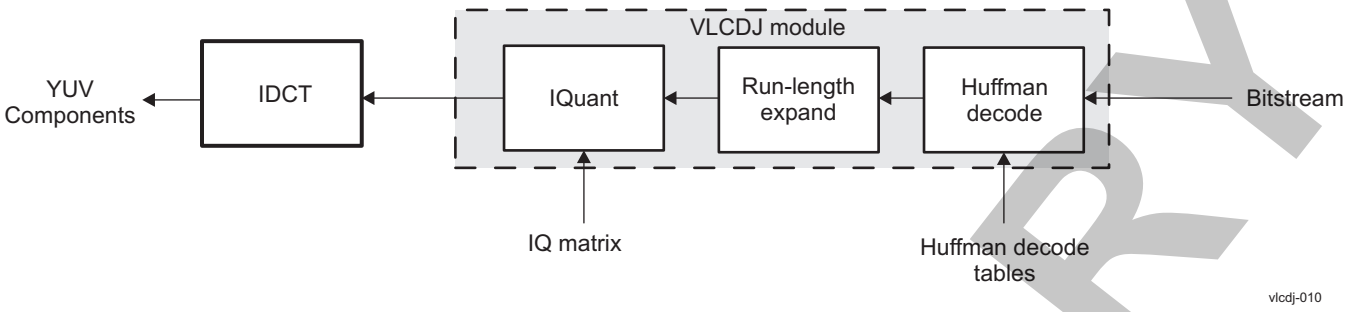
8.4.6.3.5 ISS SIMCOP VLCDJ in JPEG Decoding Flow

Decoding or decompression operates in the reverse order, as shown in Figure 8-290.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 8-290. JPEG Decoding Flow



1. In decoding, in the MCU data section, when the VLCDJ recognizes the 0xFF byte in the bitstream, it detects whether the next byte is a 0 byte. If it is, the 0 byte is removed and decoding continues as if the 0 byte is not there (the 0xFF byte is kept). If the next byte is not a 0 byte, the VLCDJ flags this as a JPEG data error. This can be caused by an earlier bitstream error that causes the module to parse outside the MCU entropy data and into markers that are not supported by the module.
2. Because the VLCDJ decodes for multiple MCUs, restart markers can occur in MCU boundaries. Restart marker detection and processing work with the 0 byte removal logic to ensure that restart markers are detected and removed correctly. When the VLCDJ detects a restart marker, it resets the DC predictors in the IQ stage.
3. The VLCDJ looks up the Huffman table to convert a variable-length bit segment into a DC size or an AC run/size pair. The number of additional bits equal to the size is extracted and the DC/AC coefficient is reconstructed. Then, zero runs are expanded.
4. IQ is performed, which is simply multiplication of the coefficients with values in the quantizer matrices.

8.4.6.3.6 Memory Interfaces

The VLCDJ has four memory interfaces (all memories are inside the SIMCOP subsystem):

- Image buffer (input DCT coefficients for encoding and output DCT coefficients for decoding)
- Quantizer memory
- Huffman memory
- Bitstream memory (output for encoding and input for decoding)

8.4.6.3.6.1 Image Buffer

An image buffer stores DCT data in the context of the VLCDJ. This is an input in encode mode and an output in decode mode.

When multiple MCUs are configured, DCT coefficients for the MCUs are stored sequentially (MCU 0 is stored first, followed by MCU 1, and so on).

Blocks in an MCU are stored sequentially; that is, block 0 first, block 1 next, and so on. There are six blocks per MCU in YUV4:2:0 format, {Y0, Y1, Y2, Y3, U, V}, and four blocks per MCU in YUV4:2:2 format, {Y0, Y1, U, V}.

The 64 DCT coefficients for each block are stored in an 8 × 8 transposed format (the companion DCT module handles the transposed format). Each coefficient, up to [–2047, 2047] in range is stored on a 16-bit word. Table 8-1479 lists the data format in each 8 × 8 block of coefficients.

Table 8-1479. Image Buffer Block Format

Byte Offset								
0	1	2	3	4	5	...	14	15
c(0, 0)		c(0, 1)		c(0, 2)		...	c(0, 7)	
c(1, 0)		c(1, 1)		c(1, 2)		...	c(1, 7)	
c(2, 0)		c(2, 1)		c(2, 2)		...	c(2, 7)

8.4.6.3.6.2 Quantizer Memory

The quantization memory stores the reciprocal of quantizers, 2^{15}/qmat[i][j] so that hardware performs multiplications rather than divisions. Each data point is stored in 16 bits.

The quantizer matrices have a fixed size, 64 16-bit elements each. The quantizer memory (QMEM) is sized to hold up to four matrices (for the recommended allocation for YUV4:2:0 and YUV4:2:2, see Table 8-1480).

Table 8-1480. Recommended QMEM Allocation for YUV4:2:0 and YUV4:2:2

Quadrant of QMEM	Address Offset (Bytes)	Contents
00	0x000	(Encode) Quantizer reciprocal for Y (2^{15}/qmat[i][j])
01	0x080	(Encode) Quantizer reciprocal for UV (2^{15}/qmat[i][j])
10	0x100	(Decode) Quantizer for Y (qmat[i][j])
11	0x180	(Decode) Quantizer for UV (qmat[i][j])

Each matrix is stored in zigzag order to make quantization and inverse quantization more efficient.

8.4.6.3.6.3 Huffman Memory

Huffman memories store Huffman encode tables and Huffman control/decode tables. For information about Huffman tables, see Section 8.4.6.3.7, *Huffman Table Organization*.

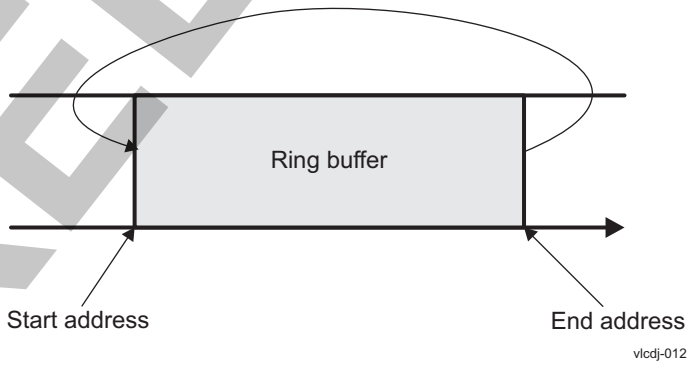
8.4.6.3.6.4 Bitstream Memory

Bitstream memory is for input/output (I/O) bitstream. Bitstream data is stored in little-endian format in the memory. Circular buffer start and end addresses are provided in registers to facilitate bitstream data management:

- VLCDJE_CBUF[11:10] START, start of ring buffer for encode mode (address must be 1 KiB aligned)
- VLCDJE_CBUF[27:26] END, end of ring buffer for encode mode (address must be 1 KiB aligned)
- VLCDJD_CBUF[11:10] START, start of ring buffer for decode mode (address must be 1 KiB aligned)
- VLCDJD_CBUF[27:26] END, end of ring buffer for decode mode (address must be 1 KiB aligned)

Figure 8-292 shows the start and end addresses of a ring buffer.

Figure 8-292. VLCDJ Ring Buffer



In encoding and decoding, a bit-level boundary defines bitstream data written (for encoding) or parsed (for decoding). To point to that boundary, bit and byte pointers are provided in the registers:

- VLCDJE_BSPTR[19:16] BITPTR (encoding)
- VLCDJE_BSPTR[11:0] BYTEPTR (encoding)
- VLCDJD_BSPTR[19:16] BITPTR (decoding)
- VLCDJD_BSPTR[11:0] BYTEPTR (decoding)

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

BYTEPTR (byte pointer) points to the byte where the boundary lies, and BITPTR (bit pointer) specifies the number of available vacant data bits (for encoding) or remaining data bits (for decoding). BITPTR is always within the range from 1 to 8, where 8 indicates that an entire byte is available for writing or reading.

For example, for encoding, if BYTEPTR = 0 and BITPTR = 8, after the hardware encodes a specified number of MCUs that together generate 30 bits, or 3 full bytes and 6 bits, BYTEPTR = 3 and BITPTR = 2. The JPEG standard requires that at the end of MCU data, any remaining bits of the last byte are padded with 1s. For example, if the last byte has 4 bits written 0101, the last byte of MCU data in the JPEG data is 0x5F.

8.4.6.3.7 Huffman Table Organization

8.4.6.3.7.1 Huffman Table for Encode Mode

Because the Huffman encode tables are compact, they are fixed relative to a common pointer:

- The Luma DC table starts at VLCDJE_VLCTBL[11:2] ADDR (12 entries × 4 = 48 bytes)
- The Luma AC table starts at VLCDJE_VLCTBL[11:2] ADDR + 48 bytes (11 × 16 x 4 = 704 bytes)
- The Chroma DC table starts at VLCDJE_VLCTBL[11:2] ADDR + 752 bytes (12 entries × 4 = 48 bytes)
- The Chroma AC table starts at VLCDJE_VLCTBL[11:2] ADDR + 800 bytes (11 × 16 × 4 = 704 bytes)

For DC tables, the index of each table corresponds to the size of the absolute value of the DC coefficient.

For AC tables, the index of each table corresponds to a formula including the size (of absolute value of nonzero AC coefficients) and the zero run: Index = SIZE × 16 + run. Because the size cannot be 0, the first 16 entries hold special symbols. EOB is at entry 0, and ZRL is at entry 15.

The size of a non-negative value is the number of bits required to represent the value (for example, a size of 4..7 = 3).

Figure 8-293 shows the organization of the Huffman encode table.

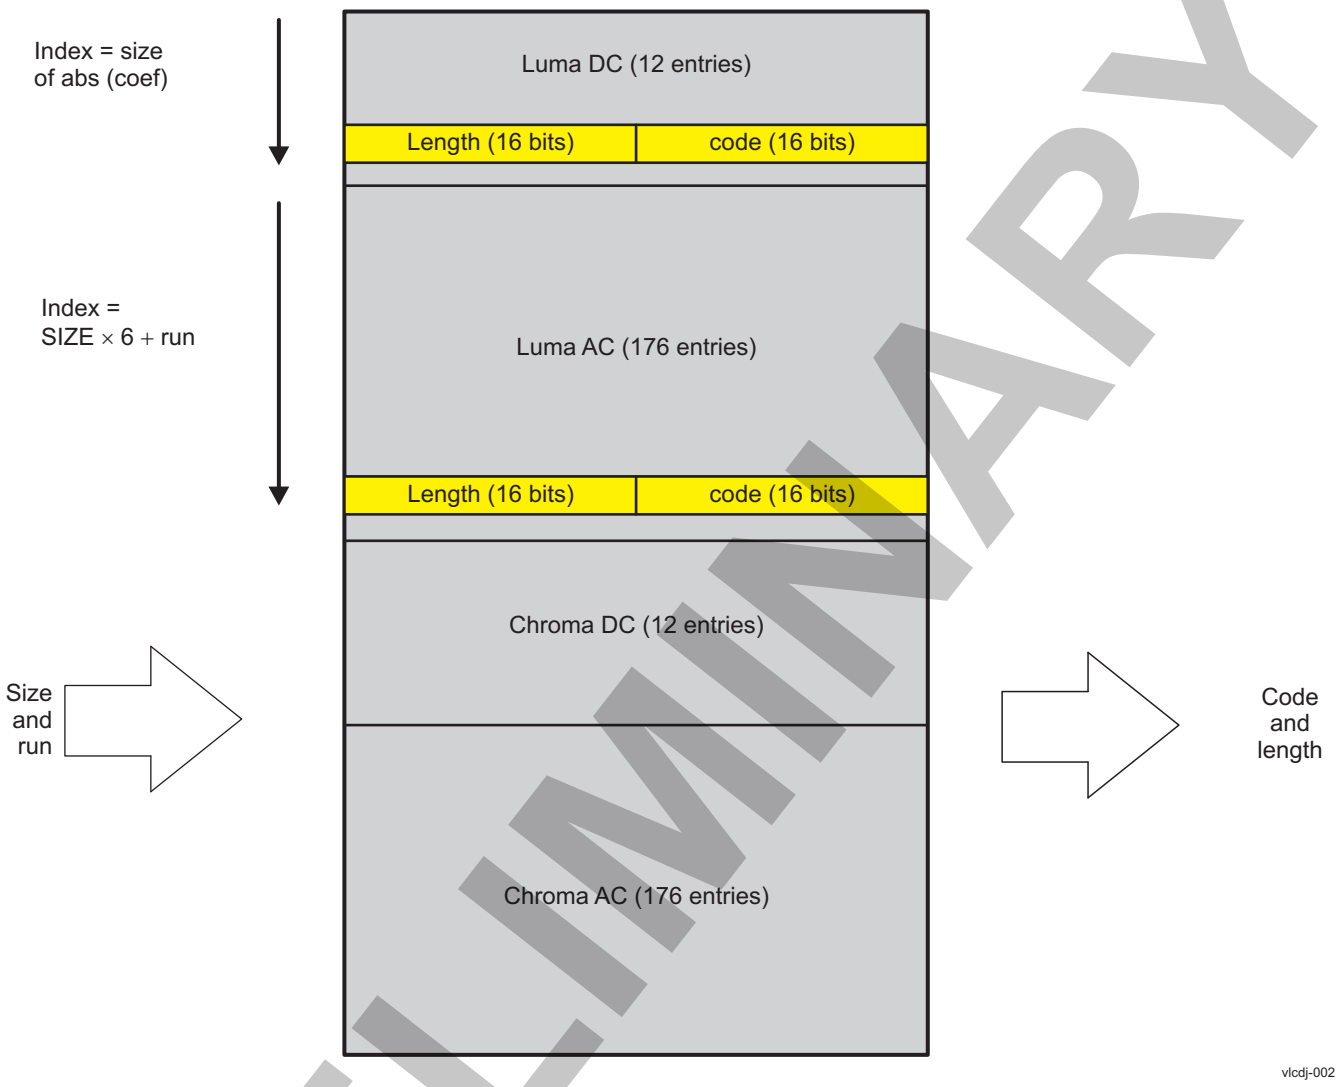
Copyright © 2013, Texas Instruments Incorporated

Figure 8-293. Huffman Encode Table Organization



8.4.6.3.8 Restart Marker

8.4.6.3.8.1 Restart Marker Insertion for Encode

As specified in the JPEG standard, the VLCDJ can insert a restart marker at a specified MCU interval (for information about restart markers, see Section 8.4.6.3.5, *VLDCJ in JPEG Decoding Flow*). Any remaining bits in the last partial byte are padded with 1s.

When enabled, the VLCDJ inserts a restart marker at the end of a group of MCUs. A partial byte is automatically padded with 1s.

8.4.6.3.8.2 Restart Marker Location Recording

To facilitate reordering of compressed JPEG data sections to achieve JPEG rotation, the VLCDJ also records the restart marker locations.

8.4.6.3.8.3 Restart Marker Handling for Decoding

Restart markers are handled automatically during MCU data decoding according to the JPEG standard. The DC predictors are reset at the MCU boundary where restart markers are present.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Because the handling of restart markers is complex, there is no check of the consistency of restart marker value or existence/nonexistence with the restart interval (which is not part of the decoder register setting). Correct JPEG files are decoded correctly. Incorrect JPEG files can escape error detection.

To decode correctly, in spite of the presence of restart markers, software must configure the VLCDJ with the correct byte pointer for the VLCDJ. To reset DC predictors to occur before an MCU, the byte pointer must point to the restart marker before the MCU data in the bitstream data. In other words, the VLCDJ does not search for the correct marker and resume MCU decoding after the marker. The VLCDJ detects the presence of the marker only at the MCU boundaries.

8.4.6.3.9 Encode/Decode Context Switching

The bitstream memory is organized as two banks of memory. When the VLCDJ performs only encoding or only decoding, the two banks are used to achieve VLCDJ and DMA concurrence, and automatic bitstream data DMA is supported.

When the VLCDJ performs one encode and one decode concurrently, both contexts can coexist in the configuration registers, because encode and decode configurations are in separate registers. The bitstream memory must be partitioned half-and-half between encode and decode. For example:

- VLCDJE_CBUF[11:10] START = 0x0
- VLCDJE_CBUF[27:26] END = 0x7FF
- VLCDJD_CBUF[11:10] START = 0x800
- VLCDJD_CBUF[27:26] END = 0xFFF

The byte pointers and the bitstream data DMA must be set up accordingly.

When the VLCDJ is encoding, the decode half of bitstream memory can be refilled by DMA. When the VLCDJ is decoding, the encode half of bitstream memory can be transferred out by DMA. Hardware does not support automatic triggering of DMA; software must submit DMA based on the byte pointer value of each context. For good SDRAM efficiency, the DMA block must be aligned correctly.

8.4.6.3.10 Using Sequential Block Mode for YUV4:4:4 Encoding/Decoding

In sequential block mode, because it deals with only one color component, the VLCDJ does the following:

- Uses DCPREDY for the DC predictor
- Uses the first quantizer matrix pointed by QM/QMR
- Starts from the first block pointed to by DCT
- Uses the first VLC/VLD table

Thus, to encode/decode YUV4:4:4 format using sequential block mode, software must switch context among Y, U, and V between initiations of the VLCDJ. Memory organization and registers are designed so that QM/QMR, DCT, and VLC/VLD tables can be swapped by changing the corresponding pointers in the registers. The DC predictor must be saved and restored.

For more information, see Section 8.4.6.4.6, *Example of YUV4:4:4 Encoding*.

8.4.6.3.11 Error Reporting

The VLCDJ can report the following decode errors:

- Invalid Huffman code
- Block exceeding 64 coefficients

NOTE: Decoding of an 0xFF byte followed by a nonzero byte is not reported as an error (for more information, see Section 8.4.6.3.5, *VLCDJ in JPEG Decoding Flow*).

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

When there is a decode error, VLCDJ operation is suspended immediately. Bit and byte pointers to the bitstream near where the error occurs are reflected in the VLCDJD_BSPTR[19:16] BITPTR and VLCDJD_BSPTR[11:0] BYTEPTR bit fields. The DCT coefficient index, in zigzag order of the task, near where the error occurs, is also reflected in a read-only bit field, VLCDJD_DCTERR[13:0] ERRPTR. For example, if decoding fails at the fifth coefficient of the third block of the VLCDJ task (which can be multiple MCUs), ERRPTR returns 2 × 64 + 4 = 195.

The IQ stage of the hardware does not stop and runs to completion. When there is a decode error, the DC predictor and decoded DCT coefficient outcomes are indeterminate.

Because the VLCDJ does not start in the middle of an MCU, software must recover from the error and configure the VLCDJ from an MCU boundary.

8.4.6.4 ISS SIMCOP VLCDJ Basic Programming Model

8.4.6.4.1 Initialization of Surrounding Modules

To initialize the VLCDJ, surrounding modules must be initialized. Table 8-1481 lists these modules.

Table 8-1481. Initialization of Surrounding Modules

Module	Minimum Required Setting	Optional Settings
CLKC	Enable the SIMCOP clock.	
Buffers	Configure VLCDJ access to the image buffer.	
SIMCOP CTRL		Configure SIMCOP CTRL to handle VLCDJ interrupts.

8.4.6.4.2 ISS SIMCOP VLCDJ Start and Register Modification During Processing

The module operation can be started with two mechanisms, depending on the status of the VLCDJ_CTRL[2] TRIG_SRC bit.

When the VLCDJ_CTRL[2] TRIG_SRC bit is set to 0 and the module is idle (the VLCDJ_CTRL[16] BUSY bit is set to 0), the module is started by setting the VLCDJ_CTRL[0] EN bit to 1. Any hardware start pulses are ignored. To simplify software control, in the same register write, changing the VLCDJ_CTRL[2] TRIG_SRC bit from 1 to 0 and setting the VLCDJ_CTRL[0] EN bit to 1 is recognized as a valid starting condition.

When the VLCDJ_CTRL[2] TRIG_SRC bit is set to 1, and the module is idle (the VLCDJ_CTRL[16] BUSY bit is set to 0), the module is started by the START_PULSE signal going active. Any software write to the VLCDJ_CTRL[0] EN bit is ignored.

During encoding, encode configuration registers must not be modified by software, while decode configuration registers can be freely modified.

During decoding, decode configuration registers must not be modified by software, while encode configuration registers can be freely modified.

8.4.6.4.3 JPEG Encoding

For JPEG encoding of a YUV4:2:0 image, eight MCUs per task, software first composes the JPEG header, which includes image dimension, YUV4:2:0 format, Huffman tables, quantizer matrices, and the start-of-scan marker and scan header, all before the MCU data. Software then sets up the encoding task, once per image, with the procedure listed in Table 8-1482.

Table 8-1482. JPEG Encoding Procedure

Step	Register/Bit Field	Value
Configure the encode configuration register.	VLCDJE_CFG[1:0] FMT	0 (YUV4:2:0 mode)
	VLCDJE_CFG[13:8] NMCUS	7 (eight MCUs)
	VLCDJE_CFG[2] RSTEN	0 (no restart marker)
Configure the DC predictor.	VLCDJE_DCPREDY[11:0] PREDY	0 (reset DC predictor for Y)
	VLCDJE_DCPREDUV[11:0] PREDU	0 (reset DC predictors for U)
	VLCDJE_DCPREDUV[27:16] PREDV	0 (reset DC predictors for V)
Configure the input and output memories.	VLCDJE_BSPTR[11:0] BYTEPTR	0 (beginning of bitstream memory)
	VLCDJE_BSPTR[19:16] BITPTR	8 (initially empty byte, thus 8 free bits)
	VLCDJE_CBUF[11:10] START	0 (bitstream starts from beginning of first quadrant of bitstream memory)
	VLCDJE_CBUF[27:26] END	3 (bitstream ends at end of fourth quadrant of bitstream memory)
	VLCDJE_DCTQM[13:4] DCT	0 (DCT coefficients at beginning of image buffer)

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 8-1482. JPEG Encoding Procedure (continued)

Step	Register/Bit Field	Value
Configure Huffman and quantizer memory pointers.	VLCDJE_DCTQM[24:23] QMR	0 (quantizer matrix reciprocal at beginning of QMEM)
	VLCDJE_VLCTBL[11:2] ADDR	0 (VLC table at beginning of HUFMEM)
Start encode with automatic ring buffer management.	VLCDJ_CTRL[1] MODE	0 (encode mode)
	VLCDJ_CTRL[0] EN	1 (start VLCDJ operation)

For each group of eight MCUs (the VLCDJ does not care if these MCUs cross multiple MCU rows), software sets the VLCDJ_CTRL[0] EN bit to 1 (restart VLCDJ operation).

Alternately, the hardware sequencer can start the VLCDJ. Usually, DMA is also configured to bring in YUV4:2:0 image data as input to DCT, and DMA, DCT, and VLCDJ are all put under control of the hardware sequencer.

Bitstream data is managed automatically between the VLCDJ and DMA throughout JPEG encoding of MCUs.

NOTE: Many registers change during the encoding of a frame, but software is not required to access these registers, because the VLCDJ manages the status information between tasks.

The last hardware task may require a smaller number of MCUs (the VLCDJE_CFG[13:8] NMCUS bit field) to adjust for the number of MCUs in the last group.

After the last VLCDJ task for the image, software must disable the automatic bitstream buffer management and prepare for the next image by setting the following values (these can be issued as a single write):

- VLCDJ_CTRL[6] RBEN = 0 (disable automatic DMA interaction)
- VLCDJ_CTRL[7] CLRRB = 1

Finally, software must pad the last data byte with bit 1s, then place an end-of-image marker after the last data byte. The VLCDJE_BSPTR[11:0] BYTEPTR and VLCDJE_BSPTR[19:16] BITPTR bit fields indicate the locations of the last data byte and bit, respectively. Software must then set up DMA to transfer out the remaining data in bitstream memory.

The number of MCUs processed by hardware per task must be set according to image buffer allocation. For example, with 8 KiB available for DCT coefficient memory, and YUV4:2:0 format, it is possible to process 8K/(16 × 16× 1.5 × 2) = 10 MCUs. Because the bitstream DMA is automatic, bitstream data does not overflow bitstream memory for this many MCUs in densely coded JPEG.

8.4.6.4.4 JPEG Decoding

For JPEG decoding of an image, software first parses the JPEG header, which includes image dimension, YUV sampling, Huffman tables, quantizer matrices, and start-of-scan marker and scan header, before the MCU data. Software then sets up DMA to load bitstream data into the first half of bitstream memory.

The Huffman tables must be processed to generate hardware control tables and decode tables for a particular JPEG file, unless the Huffman tables match previously processed tables for which the hardware control and decode tables are known. The hardware control and decode tables must be transferred to HUFMEM.

If the JPEG file is YUV4:2:0, and image buffer memory is sufficient to process eight MCUs per hardware task, software must set up the decode task, once per image, with the procedure listed in Table 8-1483.

Table 8-1483. JPEG Decoding Procedure

Step	Register/Bit Field	Value
Configure the decode configuration register.	VLCDJD_CFG[1:0] FMT	0 (YUV4:2:0 mode)

	VLCDJD_DCPREDUV[11:0] PREDU	0 (reset DC predictors for U)
	VLCDJD_DCPREDUV[27:16] PREDV	0 (reset DC predictors for V)
Configure the input and output memories.	VLCDJD_BSPTR[11:0] BYTEPTR	0 (beginning of bitstream memory)
	VLCDJD_BSPTR[19:16] BITPTR	8 (initially empty byte, thus 8 free bits)
	VLCDJD_CBUF[11:10] START	0 (bitstream starts from beginning of first quadrant of bitstream memory)
	VLCDJD_CBUF[27:26] END	3 (bitstream ends at end of fourth quadrant of bitstream memory)
	VLCDJD_DCTQM[13:4] DCT	0 (DCT coefficients at the beginning of the image buffer)
Configure Huffman and quantizer memory pointers.	VLCDJD_DCTQM[24:23] QM	0 (quantizer matrix at beginning of QMEM)
	VLCDJD_CTRLTBL[11:2] ADDR	0 (typically, control table is placed at the beginning of HUFMEM)
	VLCDJD_DCDTBL01[11:2] TBL0	30 (typically, the first decode table follows the control table, 60 shorts = 120 bytes = 30 words)
	VLCDJD_DCDTBL01[27:18] TBL1	? (where the second decode table starts)
	VLCDJD_DCDTBL23[11:2] TBL2	? (where the third decode table starts)
	VLCDJD_DCDTBL23[27:18] TBL3	? (where the fourth decode table starts)
Start decode with automatic ring buffer management.	VLCDJ_CTRL[1] MODE	1 (decode mode)
	VLCDJ_CTRL[0] EN	1 (start VLCDJ operation)

For each group of eight MCUs (the VLCDJ does not care if these MCUs cross multiple MCU rows), software sets the VLCDJ_CTRL[0] EN bit to 1 (start VLCDJ operation).

Alternately, the hardware sequencer can start the VLCDJ, as well as control buffer switches and coordinate among the VLCDJ, DCT, and DMA.

Bitstream data is managed automatically between the VLCDJ and DMA throughout JPEG encoding of MCUs.

NOTE: Many registers change during the decoding of a frame, but software is not required to access these registers, because the VLCDJ manages the status information between tasks.

The last hardware task may require a smaller number of MCUs (the VLCDJD_CFG[13:8] NMCUS bit field) to adjust for the number of MCUs in the last group.

After the last VLCDJ task for the image, software must disable the automatic bitstream buffer management and prepare for the next image by setting the following values (these can be issued as a single write):

- VLCDJ_CTRL[6] RBEN = 0 (disable automatic DMA interaction)
- VLCDJ_CTRL[7] CLRRB = 1

Any remaining bitstream data in bitstream memory afterward is harmless, because before the VLCDJ processes the next image decode, new bitstream data must be brought in, thereby overwriting the old data, and bit/byte pointers must be reset to the beginning of bitstream memory.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The number of MCUs processed by hardware per task must be set according to image buffer allocation. For example, with 16 KiB available for DCT coefficient memory, and YUV4:2:0 format, it is possible to process 16K/(16 × 16 × 1.5 × 2) = 21 MCUs. Because the bitstream DMA is automatic, there is no bitstream data underrun for this many MCUs.

8.4.6.4.5 Concurrent JPEG Encoding and Decoding

For concurrent decoding and encoding, the two operations are configured separately but similarly.

Half of bitstream memory is used for encoding (for example, the first half), and the rest is used for decoding. Automatic bitstream DMA does not work in this case, so the number of MCUs must accommodate the worst-case bitstream size per MCU.

Theoretically, the worst case is 16 bits of Huffman code + 12 additional bits per coefficient, or 28 bits per coefficient. With natural images, there are typically about 8 bits per pixel when quantizers are minimal (that is, all 1s). With 16 bits per coefficient, or 768 bytes per MCU in YUV4:2:0 (this is 24 bits per pixel and three times the typical worst case), half of bitstream memory is 2 KiB, which can safely hold two MCUs.

In this case, half of QMEM is used for encoding and half is used for decoding. Encode and decode Huffman tables are placed so that they coexist in HUFFMEM.

The Huffman tables for encoding, decoding, and quantizer matrices must be placed accordingly in HUFMEM and QMEM. Bitstream data is filled at the second half of bitstream memory for decoding.

Register fields are configured as listed in Table 8-1484.

Table 8-1484. Concurrent JPEG Encoding and Decoding

Step	Register/Bit Field	Value
Configure the encode register.	VLCDJE_CFG[1:0] FMT	0 (YUV4:2:0 mode)
	VLCDJE_CFG[13:8] NMCUS	1 (two MCUs)
	VLCDJD_CFG[2] RSTEN	0 (no restart marker)
	VLCDJE_DCPREDY[11:0] PREDY	0 (reset DC predictor for Y)
	VLCDJE_DCPREDUV[11:0] PREDU	0 (reset DC predictors for U)
	VLCDJE_DCPREDUV[27:16] PREDV	0 (reset DC predictors for V)
	VLCDJE_BSPTR[19:16] BITPTR	8 (initially empty byte, thus 8 free bits)
	VLCDJE_DCTQM[13:4] DCT	0 (DCT coefficients at beginning of image buffer)
Configure the decode register.	VLCDJD_CFG[1:0] FMT	0 (YUV4:2:0 mode)
	VLCDJD_CFG[13:8] NMCUS	1 (two MCUs)
	VLCDJD_CFG[2] RSTEN	0 (no restart marker)
	VLCDJD_DCPREDY[11:0] PREDY	0 (reset DC predictor for Y)
	VLCDJD_DCPREDUV[11:0] PREDU	0 (reset DC predictors for U)
	VLCDJD_DCPREDUV[27:16] PREDV	0 (reset DC predictors for V)
	VLCDJD_BSPTR[19:16] BITPTR	8 (initially empty byte, thus 8 free bits)
	VLCDJD_DCTQM[13:4] DCT	0 (DCT coefficients at the beginning of the image buffer)
Configure the byte pointer to bitstream memory.	VLCDJE_BSPTR[11:0] BYTEPTR	0 (beginning of bitstream memory)
	VLCDJD_BSPTR[11:0] BYTEPTR	0x800 (beginning of bitstream memory second half)
Configure the bitstream memory partition.	VLCDJE_CBUF[11:10] START	0 (bitstream starts at beginning of first quadrant of bitstream memory)
	VLCDJE_CBUF[27:26] END	1 (bitstream ends at end of second quadrant of bitstream memory)
	VLCDJD_CBUF[11:10] START	2 (bitstream starts at beginning of third quadrant of bitstream memory)
	VLCDJD_CBUF[27:26] END	3 (bitstream ends at end of fourth quadrant of bitstream memory)

Table 8-1484. Concurrent JPEG Encoding and Decoding (continued)

Step	Register/Bit Field	Value
Configure the quantizer matrix pointer.	VLCDJE_DCTQM[24:23] QMR	0 (quantizer matrix at beginning of QMEM)
	VLCDJD_DCTQM[24:23] QMR	2 (quantizer matrix at second half of QMEM)
Configure Huffman tables.	VLCDJE_VLCTBL[11:2] ADDR	0 (VLC table at beginning of HUFMEM)
	VLCDJD_CTRLTBL[11:2] ADDR	376 (after VLC table, 2 × (24 + 352) shorts = 376 words)
	VLCDJD_DCDTBL01[11:2] TBL0	406 (after control table of 30 words)
	VLCDJD_DCDTBL01[27:18] TBL1	? (where the second decode table starts)
	VLCDJD_DCDTBL23[11:2] TBL2	? (where the third decode table starts)
	VLCDJD_DCDTBL23[27:18] TBL3	? (where the fourth decode table starts)

Software sets the following values to start encoding:

- VLCDJ_CTRL[1] MODE = 0 (encode mode)
- VLCDJ_CTRL[0] EN = 1 (start VLCDJ operation)

When the VLCDJ completion interrupt is detected by software, encoding is complete and software must service the encoded bitstream data in the first half of bitstream memory, letting hardware access the second half of the bitstream for decoding. Software sets up bitstream writes to transfer the encoded bitstream from bitstream memory[0] to bitstream memory[128 × (VLCDJE_BSPTR[11:0] BYTEPTR/128)] (rounding down to 128-byte alignment improves SDRAM efficiency). Software must identify the bitstream data already transferred out, for the next round of servicing encoded bitstream data. Software must also service to-encode input data to the DCT.

After kicking off encode DMAs, without waiting for DMA completion, software must set the following values to start VLCDJ decoding in parallel with the DMA:

- VLCDJ_CTRL[1] MODE = 1 (decode mode)
- VLCDJ_CTRL[0] EN = 1 (start VLCDJ operation)

When the VLCDJ completion interrupt is detected by software, decoding is complete and software must service the decoded bitstream data in the second half of bitstream memory, letting hardware access the first half of the bitstream for encoding. Software sets up bitstream writes to transfer the bitstream to be decoded from bitstream memory[0] to bitstream memory[128 × (VLCDJD_BSPTR[11:0] BYTEPTR/128)] (rounding down to 128-byte alignment improves SDRAM efficiency). Software must identify the bitstream data already transferred in, for the next round of servicing bitstream data to be decoded. Software must also service decoded image data in the output image buffer of the DCT.

After kicking off decode DMAs, without waiting for DMA completion, software must start VLCDJ encoding in parallel with the DMA.

Software must continue to alternate between encoding and decoding until the image completes.

Figure 8-294 shows the concurrence schedule for JPEG encoding and decoding.

Figure 8-294. Concurrence Schedule for JPEG Encoding and Decoding

DMA	E[0]		E[1]		E[2]		E[3]

DCT		E[0]		E[1]	D[0]	E[2]	D[1]	E[3]	D[2]		D[3]	
VLCD			E[0]	D[0]	E[1]	D[1]	E[2]	D[2]	E[3]	D[3]		
DMA				E[0]		E[1]		E[2]		E[3]		
out						D[0]		D[1]		D[2]		D[3]

vlcdj-007

Management of bitstream I/O and image I/O is heavy in intervals of only two MCUs. It is better to run only encoding for many MCUs, switch context, and then run decoding for many MCUs.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

When running JPEG transcoding, decoding a picture and re-encoding it, to adjust quantizers and/or remove/insert restart markers, it can be more efficient to run encode and decode concurrently in VLCDJ, skipping DCT and image I/O DMA altogether. In this case, software handles only bitstream data I/O, which is more manageable.

Figure 8-295 shows the concurrence schedule.

Figure 8-295. Concurrence Schedule for JPEG Transcoding

DMA in	D[0]		D[1]		D[2]		D[3]			
VLCD		D[0]	E[0]	D[1]	E[1]	D[2]	E[2]	D[3]	E[3]	
DMA out				E[0]		E[1]		E[2]		E[3]

vlcdj-008

8.4.6.4.5.1 DMA and Buffer Manual Management

When the VLCDJ performs one encode and one decode concurrently, both contexts can coexist in the configuration registers, because encode and decode configurations are in separate registers. The bitstream memory must be partitioned half-and-half between encode and decode:

- VLCDJE_CBUF[11:10] START = 0 (0x0)
- VLCDJE_CBUF[27:26] END = 1 (0x7FF)
- VLCDJD_CBUF[11:10] START = 2 (0x800)
- VLCDJD_CBUF[27:26] END = 3 (0xFFF)

The byte pointers and the bitstream data DMA must be set up accordingly.

When the VLCDJ is encoding, the decode half of the bitstream memory can be refilled by DMA. When the VLCDJ is decoding, the encode half of the bitstream memory can be transferred out by DMA. Hardware does not support automatic triggering of DMA; software must submit DMA based on the byte pointer value of each context. For greater SDRAM efficiency, the DMA block must be aligned correctly. For example, the pseudo code that sets up the DMA for an encode task may appear as:

```
new_dma_ptr = VLCDJ_BSPTR.BYTEPTR & ~0x3F; // align to 64-byte

if (new_dma_ptr > saved_dma_ptr)
{
 setup_dma(saved_dma_ptr, new_dma_ptr - saved_dma_ptr);
 // start DMA at saved_dma_ptr, length = new_dma_ptr - saved_dma_ptr
}
else // wraps around, need to DMA 2 blocks
{
 setup_dma(saved_dma_ptr, 0x800 - saved_dma_ptr);
 setup_dma(saved_dma_ptr, new_dma_ptr);
}

saved_dma_ptr = new_dma_ptr;
```

This DMA setup can be carried out concurrently with VLCDJ operation; thus, this code is executed with each encode or decode task. When the VLCDJ is encoding, software can access the decode bit/byte points to set up DMA for decoding, and vice versa.

Because hardware stalling does not work in this case, the number of MCUs must be configured so that in the worst case there is no bitstream data overrun or underrun.

The bitstream buffer can be allocated at a quarter of bitstream memory granularity, or 1 KiB. This allows at most four separate buffers to coexist in bitstream memory.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

If multiple encode and/or decode threads are performed concurrently, software must save and restore the appropriate configuration registers. The register map has common registers in one group, encode registers in another group, and decode registers in a third group. Bitstream memory partitioning and corresponding DMA submission are left to software.

8.4.6.4.6 Example of YUV4:4:4 Encoding

The following pseudo code shows the general sequence involved in YUV4:4:4 encoding. Decoding can be similarly derived.

```
encode_yuv444()
{
 VLCDJ_CTRL[1] MODE = 0; /* encode */
 VLCDJE_CFG[1:0] FMT = 2; /* sequential block mode */
 VLCDJE_CFG[13:8] NMCUS = 0; /* 1 block at a time */
 pred_y = 0;
 pred_u = 0;
 pred_v = 0;

 for (i=0; i<num_mcus; i++)
 {
 VLCDJE_DCPREDY = pred_y; /* restore Y context */
 VLCDJE_DCT = DCT_Y;
 VLCDJE_QMR = QMR_Y;
 VLCDJE_VLCTBL = VLC_Y;

 VLCDJ_CTRL[0] EN = 1; /* kick off VLCDJ for Y */

 pred_y = VLCDJE_DCPREDY; /* save Y context */
 VLCDJE_DCPREDY = pred_u; /* restore U context */
 VLCDJE_DCT = DCT_U;
 VLCDJE_QMR = QMR_UV;
 VLCDJE_VLCTBL = VLC_UV;

 VLCDJ_CTRL[0] EN = 1; /* kick off VLCDJ for U */

 pred_u = VLCDJE_DCPREDY; /* save U context */
 VLCDJE_DCPREDY = pred_v; /* restore V context */
 VLCDJE_DCT = DCT_V;

 VLCDJ_CTRL[0] EN = 1; /* kick off VLCDJ for V */

 pred_v = VLCDJE_DCPREDY; /* save V context */
 }
}
```

8.4.6.4.7 Example of Huffman Encode and Decode Tables

8.4.6.4.7.1 Huffman Encode Table

Sample JPEG Luma DC encode table:

```
unsigned short jpeg_dc_y[24] =
{
 0x0000,0x0002,0x0002,0x0003,0x0003,0x0003,0x0004,0x0003,
 0x0005,0x0003,0x0006,0x0003,0x000e,0x0004,0x001e,0x0005,
 0x003e,0x0006,0x007e,0x0007,0x00fe,0x0008,0x01fe,0x0009
};
```

Table 8-1485 corresponds to Table 17 in the JPEG standard *ISO/IEC JTC1/SC29/WG10 Standard 10918-1 (JPEG), Information Technology – Digital Compression and Coding of Continuous-Tone Still Images – Requirements and Guidelines.*

PRELIMINARY

Table 8-1485. Sample Luma DC Huffman Code Table

Category	Code Length	Code Word
0	2	00
1	3	010
2	3	011
3	3	100
4	3	101
5	3	110
6	4	1110
7	5	11110
8	6	111110
9	7	1111110
10	8	11111110
11	9	111111110

For example if we want to code a DC coefficient value of –5:

Use abs(–5) = 5 to select a size of 3. Look up the encode table to find:

- jpeg_dc_y[2 × 3] = 4 (code)
- jpeg_dc_y[2 × 3 + 1] = 3 (length)

Thus, the VLCDJ adds 100 to the bitstream as the Huffman code of the size.

The additional bits for negative coefficients are ones complement of the absolute value, so for –5, this is 010, or 2. After the Huffman code of the size, the VLCDJ adds 010 to the bitstream.

The AC coefficient table is the same, except that the VLCDJ uses 16 × size + run to index the encode table.

8.4.6.4.7.2 Huffman Decode Tables

Sample JPEG Luma DC control and decode tables:

```
unsigned short jpeg_dc_y_ctl_tbl[13]=
{
 0x0000,0x0000,0x0000,0x0000,0x1800,0x2001,0x2802,0x3003,
 0x3804,0x4005,0x4806,0x4806,0x4806
};

unsigned short jpeg_dc_y_dcd_tbl[14]=
{
 0x0000,0x480b,0x400a,0x3809,0x3008,0x2807,0x2006,0x1805,
 0x1804,0x1803,0x1802,0x1801,0x1000,0x1000
};
```

These tables contain the same information as Table 8-1485, which complies with the JPEG standard.

8.4.7 ISS SIMCOP Rotation Accelerator (ROT) Module

This section describes the rotation accelerator (ROT) module in the still-image coprocessor (SIMCOP) subsystem.

8.4.7.1 ISS SIMCOP ROT Overview

The rotation accelerator (ROT) module is intended to be used in the still-image coprocessor (SIMCOP) to perform block data rotation and data shifting from one SIMCOP local memory to another SIMCOP local memory. The following formats and operations are supported:

- YUV4:2:2 and generic 8-/16-/32-bit data block rotation by 90, 180, and 270 degrees
- YUV4:2:0 rotation by 90, 180, and 270 degrees
- Multiple-block rotation
- Data block shifting
- Data block horizontal circular shifting

The ROT supports a simple 1-block-per-initiation interaction, and includes a microcontroller unit (MCU) software-writable enable bit and hardware trigger signal to start the processing (see Section 8.4.7.3.7, *ISS SIMCOP ROT Synchronization*). It relies on external direct memory access (DMA) for transfers, and can work with the MCU or hardware sequencer to coordinate between transfer and computation.

The ROT has an input and output memory interface (see Figure 8-298). The rotation and horizontal-shifting operations read from the input memory and write to the output memory. The module connects to an input memory of up to 16 KiB (2048 × 64-bit), and an output memory of up to 16 KiB (2048 × 64-bit) using synchronous single-port memory interface.

Figure 8-296 is an overview of the ROT.

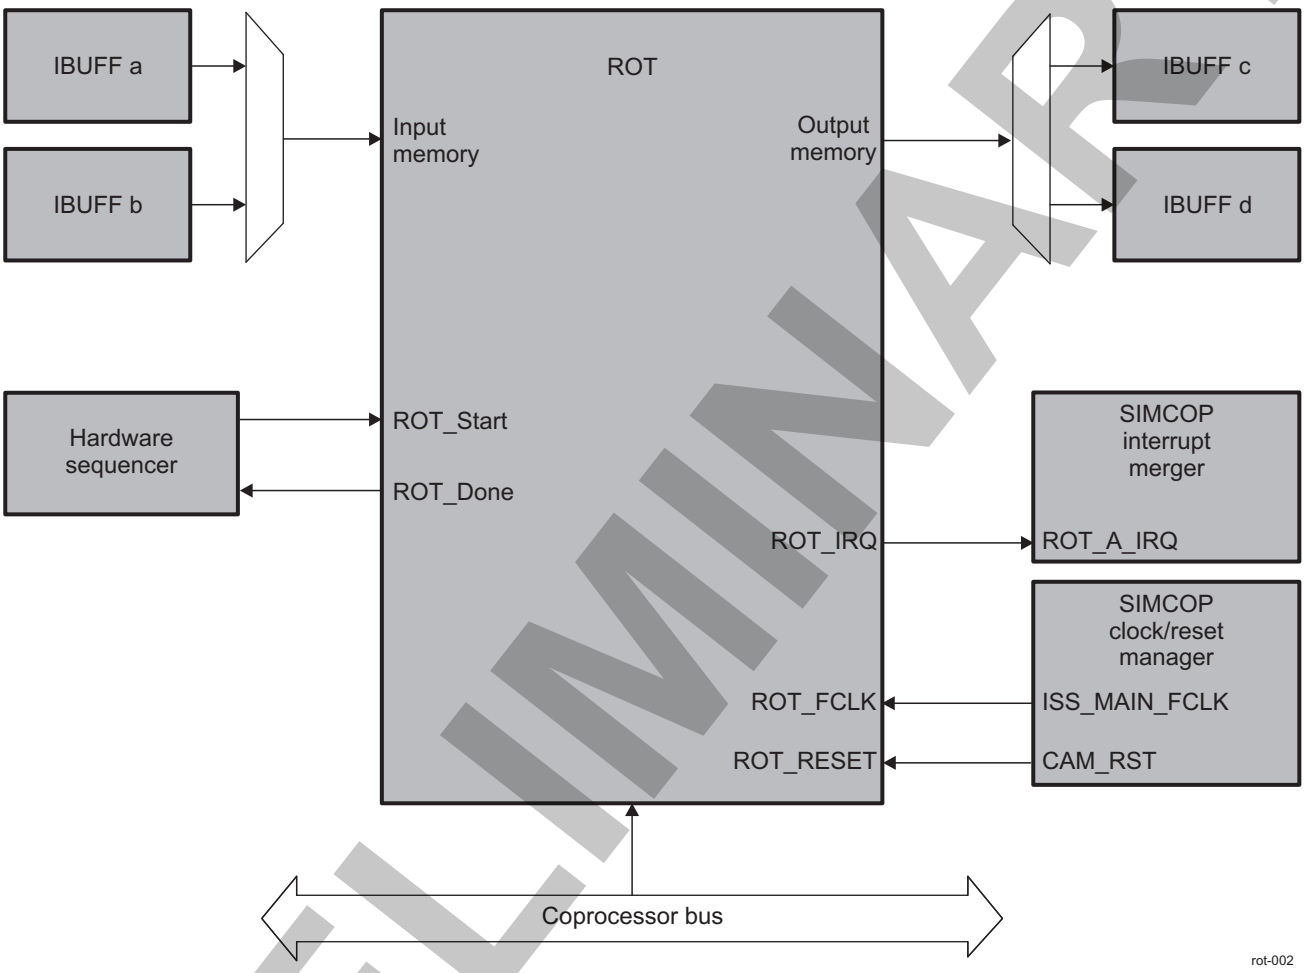
8.4.7.3 ISS SIMCOP ROT Module Functional Description

8.4.7.3.1 ISS SIMCOP ROT Module Block Diagram

Figure 8-298 shows the block diagram of the ROT.

Figure 8-298. ISS SIMCOP ROT Module Block Diagram



8.4.7.3.2 ISS SIMCOP ROT Module Clock Configuration

The ROT receives a functional clock (ISS_MAIN_FCLK) from the ISS SIMCOP. The configuration clock is derived from the functional clock and interconnect clock enable signal (the ROT_CFG[9] AUTOGATING bit).

8.4.7.3.3 ISS SIMCOP ROT Module Reset

The ROT receives an asynchronous hardware reset signal (CAM_RST) from the ISS SIMCOP.

8.4.7.3.4 ISS SIMCOP ROT Module Power Management

The ROT uses clock autogating to conserve power. When a subblock is not in use, the corresponding clock tree is gated. The ROT_CFG[9] AUTOGATING bit controls whether autogating is enabled.

8.4.7.3.5 ISS SIMCOP ROT Module Interrupt Requests

One interrupt output line, ROT_A_IRQ, is used as a sideband signal of the interconnect slave port. This signal is connected to the SIMCOP interrupt merger. See Section 8.1.2.1.1, *Interrupt Merger*.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

8.4.7.3.6 ISS SIMCOP ROT Module DMA Requests

The ROT has no DMA requests from the module.

8.4.7.3.7 ISS SIMCOP ROT Synchronization

The ROT has a simple one-block-per-task interaction with outside logic/microprocessor unit (MPU). The module can be started by setting the ROT_CTRL[0] EN bit to 0x1, or through the ROT_START signal of the hardware sequencer interface. When the ROT completes the specified rotation or data shift task, it sends a pulse on the ROT_DONE signal and, when the interrupt is enabled, sends a pulse on the ROT_A_IRQ interrupt output.

The ROT_CFG[8] TRIG_SRC bit specifies to which source the hardware must respond:

- When the module is idle and the ROT_CFG[8] TRIG_SRC bit is set to 0x0, hardware responds to the memory mapped register (MMR) mechanism, and any pulses on the start signal are ignored.
- When the module is idle and the ROT_CFG[8] TRIG_SRC bit is set to 0x1, hardware responds to the hardware start signal, and any write operation to the enable bit field is ignored.

When the module is busy, both triggering mechanisms are ignored.

8.4.7.3.8 ISS SIMCOP ROT Module Formats and Operations

The ROT module supports the formats and operations described in the following sections.

8.4.7.3.8.1 ISS SIMCOP ROT YUV4:2:0 and Generic 8-/16-/32-Bit Data Block Rotation

Rotation of YUV4:2:0 and generic 8-bit, 16-bit, 32-bit data blocks is straightforward. None of the data points are altered; each data point is copied to an appropriate address location. Zero-degree rotation is included for completeness of the programming model, and involves only data copy.

When YUV4:2:0 data have separate Y and UV processing and must be separately rotated, Y data can use generic 8-bit data rotation, and UV data can use generic 16-bit data rotation.

8.4.7.3.8.2 ISS SIMCOP ROT YUV4:2:2 Rotation

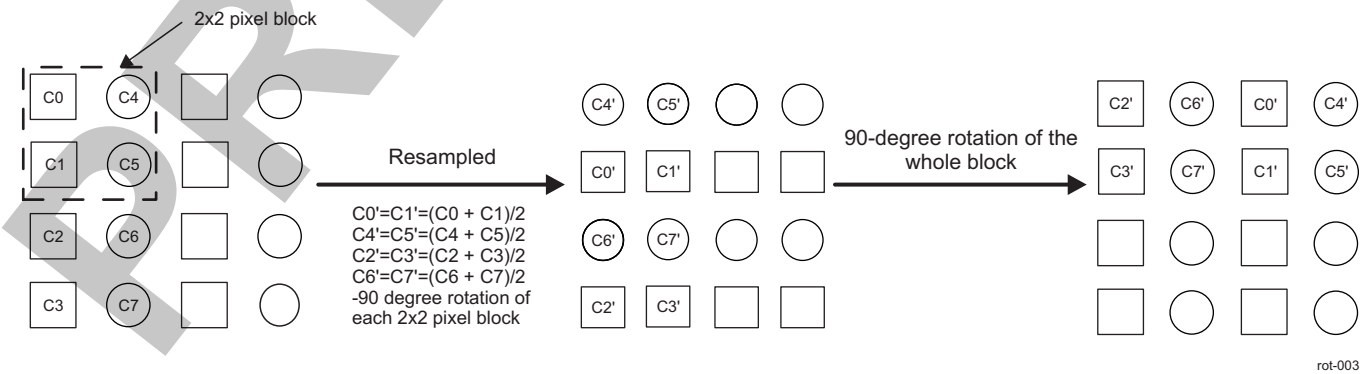
Various rotation cases of YUV4:2:2 data are described in the following and shown in Figure 8-299 through Figure 8-301 using 4 × 4-pixel block as an example.

The degree of rotation is defined as rotating clockwise. For 90-degree rotation:

- The two U samples in each 2 × 2-pixel input block are averaged and then replicated to provide the two U samples in the 2 × 2-pixel output block
- V samples - processed in the same way.

Thus, each 2N × 2N-pixel output block depends on only one 2N × 2N-pixel input block. After resampling every 2 × 2-pixel block, it is rotated –90 degrees, and then the whole 2N × 2N block is rotated 90 degrees.

Figure 8-299. ISS SIMCOP ROT 90-Degree Rotation of YUV4:2:2 Data

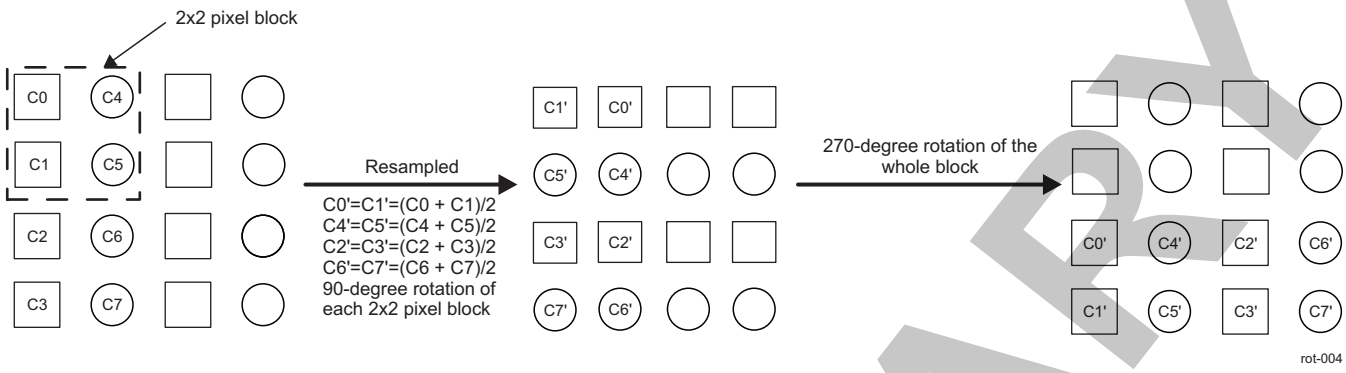


The same algorithm is used for 270-degree rotation.

Copyright © 2013, Texas Instruments Incorporated

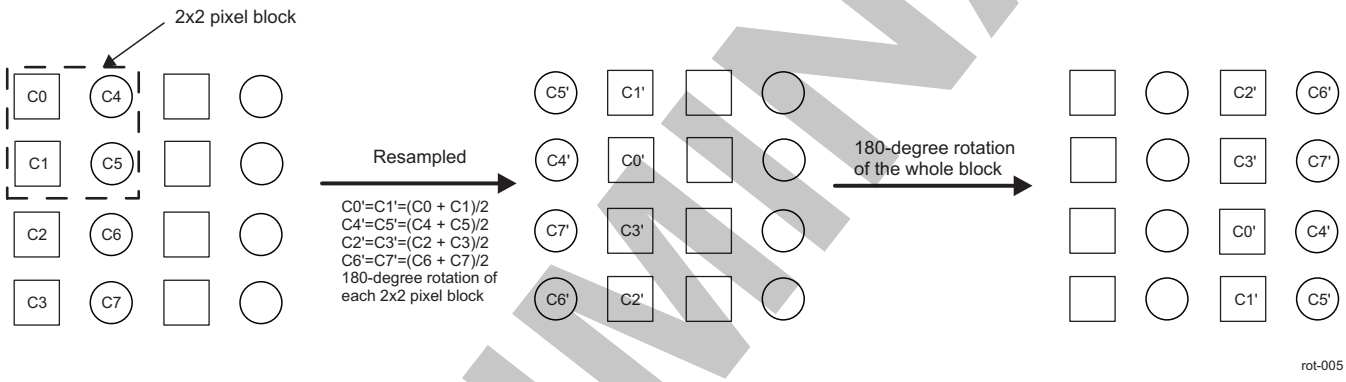
PRELIMINARY

Figure 8-300. ISS SIMCOP ROT 270-Degree Rotation of YUV4:2:2 Data



For 180-degree rotation, there is no arithmetic operation; chroma values are simply shifted horizontally before being rotated.

Figure 8-301. ISS SIMCOP ROT 180-Degree Rotation of YUV4:2:2 Data



NOTE: The intermediate process of 2 × 2 pixel block rotation, represented in the middle section in Figure 8-299 through Figure 8-301, does not involve data storage and reading into memory. That middle section is for better visualization of the process. The whole process is performed with a single memory reading and writing.

Zero-degree rotation is included for completeness of programming model, and involves only data copy.

8.4.7.3.8.3 ISS SIMCOP ROT Multiple-Block Rotation

For generic 8-/16-/32-bit data rotation and YUV4:2:0/4:2:2 rotation, multiple-block operation per hardware task is supported.

Figure 8-302 through Figure 8-305 show the multiple-block rotation feature.

The multiple blocks are in the horizontal dimension, and the blocks are horizontally adjacent to one another. In other words, in the source data and 180-degree rotated data, address offset between blocks is the source block width times the data size.

In the 90-degree and 270-degree rotated data, address offset is the source block height times the data size. The source/destination line offsets must be sufficiently large to accommodate the multiple blocks.

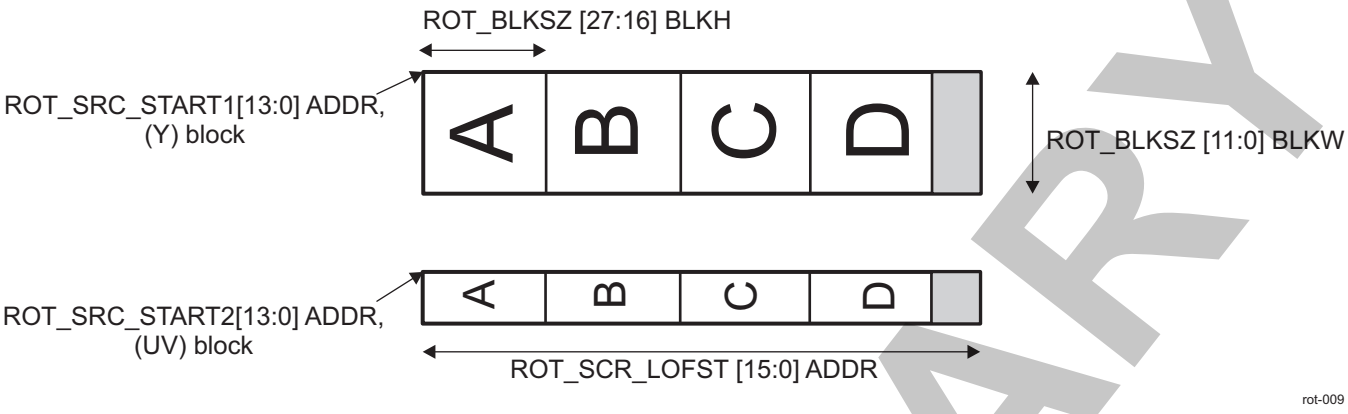
Figure 8-305. ISS SIMCOP ROT 270-Degree Block Rotation



The operation is configured with these parameters:

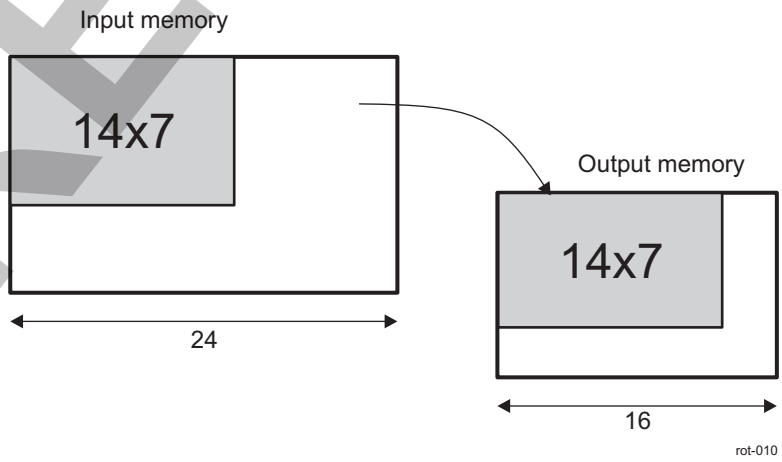
- ROT_CFG[2:0] OP (rotation orientation)
- ROT_CFG[6:4] FMT (data format)
- ROT_CFG[15:12] NBLKS (number of blocks minus 1; register value of 0 means one block, etc.)
- ROT_BLKSZ[11:0] BLKW (width of each block; all blocks are of the same width/height)
- ROT_BLKSZ[27:16] BLKH (height of each block)
- ROT_SRC_START1[13:0] ADDR (starting address of the first input block)
- ROT_SRC_LOFST[15:0] LOFST (line offset of input block)
- ROT_DST_START1[13:0] ADDR (starting address of the first output block)
- ROT_DST_LOFST[15:0]LOFST (line offset of output block)
- ROT_SRC_START2[13:0] ADDR (starting address of the first input UV block, if format is YUV4:2:0)
- ROT_DST_START2[13:0] ADDR (starting address of the first output UV block, if format is YUV4:2:0)

8.4.7.3.8.4 ISS SIMCOP ROT Data-Block Shifting

The ROT supports shifting of 2-dimensional (2D) data blocks in 8-bit granularity. This function is intended to supplement the SIMCOP DMA module, which operates on 128-bit alignment.

Figure 8-306 is an example of a 14 × 7-byte data block copied from one location in input memory to another location in output memory.

Figure 8-306. ISS SIMCOP ROT Data-Block Shifting Example



The following parameters are specified:

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- ROT_BLKSZ[11:0] BLKW = 14 (in bytes)
- ROT_BLKSZ[27:16] BLKH = 7 (in rows)
- ROT_SRC_LOFST[15:0] LOFST = 24 (in bytes)
- ROT_DST_LOFST[15:0] LOFST = 16 (in bytes)

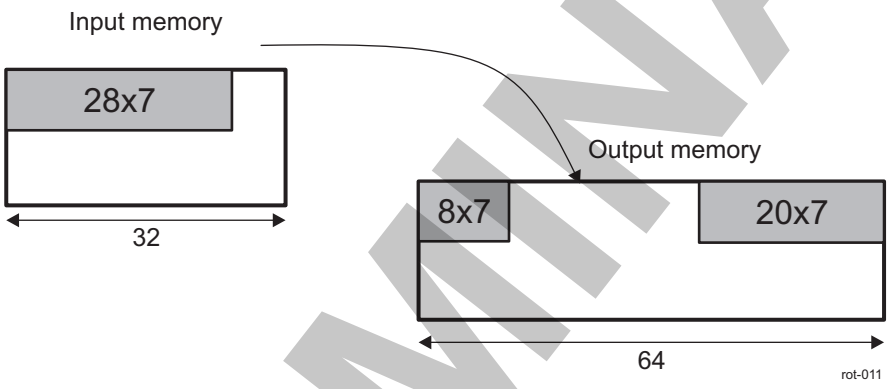
NOTE: This can be used to shift horizontally as well as vertically.

8.4.7.3.8.5 ISS SIMCOP ROT Data-Block Horizontal Circular Shifting

The ROT supports shifting of 2D data blocks in 8-bit granularity, with horizontal circular buffer addressing. This function is intended to supplement the SIMCOP DMA module, which operates on 128-bit alignment.

Figure 8-307 is an example of a 28 x 7-byte data block copied from one location in input memory to another location in output memory, and horizontal wrap-around occurs in the output memory.

Figure 8-307. ISS SIMCOP ROT Horizontal Circular Shifting Example



The following parameters are specified:

- ROT_BLKSZ[11:0] BLKW = 28 (in bytes)
- ROT_BLKSZ[27:16] BLKH = 7 (in rows)
- ROT_SRC_LOFST[15:0] LOFST = 32 (in bytes)
- ROT_DST_LOFST[15:0] LOFST = 64 (in bytes)

Wrapping around is allowed in the input memory, in the output memory, or in both. For this mode of operation, the line offset of the source and destination must be a power of 2, and at least 32 bytes. Source and destination line offsets can be different. This function is used to handle misaligned SDRAM data. The example that follows in this section shows that the line offset is at least the minimal transfer width, or the SDRAM burst. For target applications, 32 bytes is the minimal burst size to support.

NOTE: This can be used to shift horizontally as well as vertically. Input and output blocks can also have different line offsets.

This mode of operation is intended to be used to manage 2D data blocks that are out of SDRAM alignment (for example, to crop out the left-most 2 pixels of the ISP YUV4:2:2 output image before JPEG compression). Assume that the ISP output is 64-byte SDRAM burst-aligned; thus, the starting address for JPEG input is 4 bytes out of alignment. Without the horizontal circular shifting function, the best solution is to use wide data blocks (for example, 128 pixels = 256 bytes wide) to reduce the bandwidth penalty of misalignment (costing five bursts to get four bursts worth of data). With horizontal circular shifting, the bandwidth penalty can be eliminated. In this example, the SIMCOP DMA is configured to transfer aligned data, and the ROT is used to perform the crop-out. A memory transaction log would be:

- The DMA writes columns 0–63, starting at byte address 0.
- The DMA writes columns 64–127, starting at byte address 64.
- The ROT module reads columns 4–67, starting at byte address 4.

Copyright © 2013, Texas Instruments Incorporated
PRELIMINARY

- The DMA writes columns 128–191, starting at byte address 0.
- The ROT module reads columns 68–131, starting at byte address 68, and so on.

Figure 8-308 shows the data movement by the DMA and the ROT.

8.4.7.4 ISS SIMCOP ROT Module Programming Guide

8.4.7.4.1 ISS SIMCOP ROT Module Low-Level Programming Models

This section describes the low-level programming sequences for configuration and use of the ROT.

8.4.7.4.1.1 ISS SIMCOP ROT Global Initialization

8.4.7.4.1.1.1 ISS SIMCOP ROT Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the ROT is to be used for the first time after a device reset. Initialization of surrounding modules is based on the integration and environment of the module.

Table 8-1535 describes the global initialization of the surrounding modules.

Table 8-1535. ISS SIMCOP ROT Global Initialization of Surrounding Modules

Surrounding Modules	Comments
SIMCOP (clock management)	The ROT functional clock must be enabled. See Section 8.4.7.3.2, *ISS SIMCOP ROT Module Clock Configuration*.
SIMCOP (power management)	The ROT must be enabled (SIMCOP_CLKCTRL[7] ROT_A). See Section 8.4.1.2.1, *ISS SIMCOP Local Power and Clock Management* .
Buffers	Configure the ROT access to the image buffer inside the SIMCOP_HWSEQ_STEP_SWITCH_i register. See Section 8.4.2, *ISS SIMCOP Hardware Sequencer and Buffers Module*.
SIMCOP IRQ merger	Configure SIMCOP to handle the ROT interrupts. See Section 8.1.2.1.1, *Interrupt Merger*
SIMCOP hardware sequencer	Configure the hardware sequencer to activate the ROT. See Section 8.4.2,*ISS SIMCOP Hardware Sequencer and Buffers Module*.

8.4.7.4.1.1.2 ISS SIMCOP ROT Global Initialization

Table 8-1536 describes the global initialization of the ROT.

Table 8-1536. ISS SIMCOP ROT Global Initialization of the ROT

Step	Register/Bit Field/Programming Model	Value
Enable the ROT module.	ROT_CTRL[0] EN	0x0

8.4.7.4.1.2 ISS SIMCOP ROT Operational Modes Configuration

8.4.7.4.1.2.1 ISS SIMCOP ROT Rotation

The proper value for the trigger source bit (ROT_CFG[8] TRIG_SRC) is set depending on whether the operation is to be triggered by software, writing to MMR, or by the hardware sequencer. Table 8-1537 lists the procedure to set the value of the trigger source bit.

Table 8-1537. ISS SIMCOP ROT Trigger Source Bit Value

Step	Register/Bit Field/Programming Model	Value
Configure the degree of rotation.	ROT_CFG[2:0] OP	xxx
Configure the data format.	ROT_CFG[6:4] FMT	xxx
Specify the block width and height.	ROT_BLKSZ[11:0] BLKW ROT_BLKSZ[27:16] BLKH	xxx
Specify the input and output starting addresses.	ROT_SRC_START1[13:0] ADDR, ROT_DST_START1[13:0] ADDR	xxx
Specify the line offsets.	ROT_SRC_LOFST[15:0] LOFST, ROT_DST_LOFST[15:0] LOFST	xxx

PRELIMINARY

Table 8-1537. ISS SIMCOP ROT Trigger Source Bit Value (continued)

Step	Register/Bit Field/Programming Model	Value
For UV data of YUV4:2:0, input and output second starting addresses.	ROT_SRC_START2[13:0] ADDR, ROT_DST_START2[13:0] ADDR	xxx

8.4.7.4.1.2.2 ISS SIMCOP ROT Data-Block Shifting

Table 8-1538 lists the bit field values for data-block shifting.

Table 8-1538. ISS SIMCOP ROT Data-Block Shifting

Step	Register/Bit Field/Programming Model	Value
Configure shifting.	ROT_CFG[2:0] OP	xxx
Set the data shifting block.	ROT_CFG[6:4] FMT	xxx
Specify the block width and height.	ROT_BLKSZ[11:0] BLKW, ROT_BLKSZ[27:16] BLKH	xxx
Specify the input and output starting addresses.	ROT_SRC_START1[13:0] ADDR, ROT_DST_START1[13:0] ADDR	xxx
Specify the line offsets.	ROT_SRC_LOFST[15:0] LOFST, ROT_DST_LOFST[15:0] LOFST	xxx

Once the input data and output buffer are available, the ROT_CTRL[0] EN bit is set to 1 to trigger the operation through software. Alternatively, DMA transfer(s) and the hardware sequencer are configured to trigger the ROT with the hardware start signal when appropriate.

9.1 Face Detect Overview

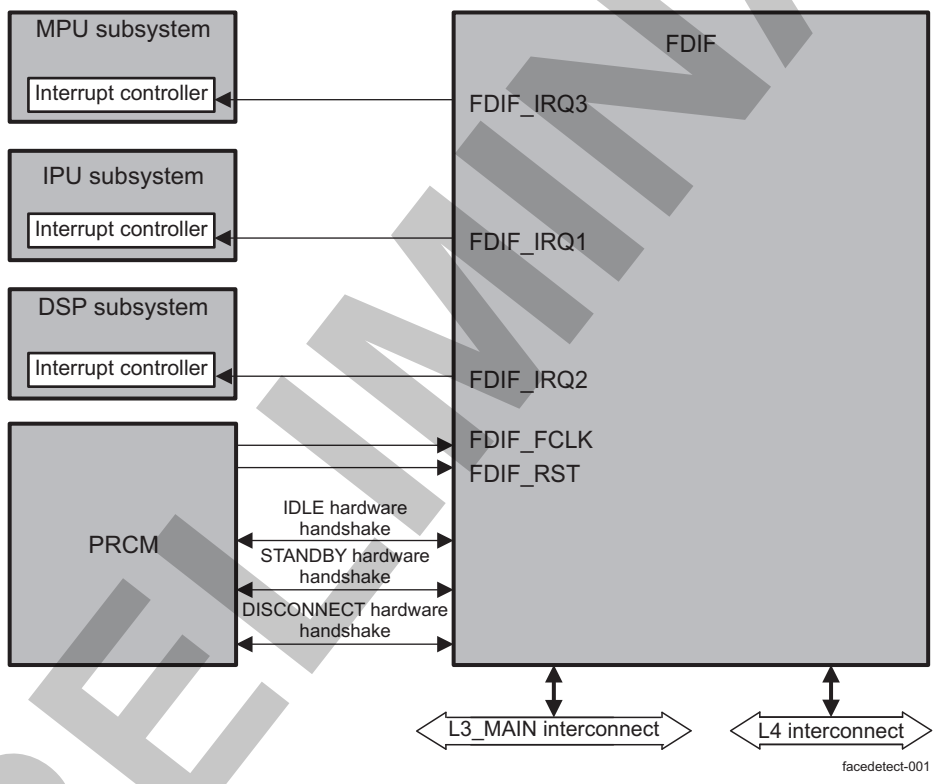
The FDIF module performs face detection within a picture stored in memory (QVGA luminance data resolution). This module is typically used for video encoding, face-based priority auto-focusing, or red-eye removal.

The face detect (FD) core is a stand-alone module: it embeds its own direct memory access (DMA) engine for accessing data in memory. The FD core is under microprocessor unit (MPU) control for its initialization and to start the processing operation.

The FD core supports single input resolution (QVGA) in a single format (8-bit Luma). The FD core requires that the input image is stored in synchronous dynamic random access memory (SDRAM). The core also requires working memory mapped in SDRAM. The input image data (320 × 240) requires 75KiB for the SDRAM and 51.25KiB for the working memory.

Figure 9-1 is an overview of the FDIF. Three interrupt lines go to the three central processing units (CPUs) to allow control of the FD core module by different processors, but only one interrupt at a time can be active. The three interrupt lines provide flexibility for controlling the module.

Figure 9-1. Face Detect Highlight



9.1.1 Main Features

The FDIF has the following features:

- Two interconnects interface:
  - 32-bit-wide level 4 (L4) interface for register configuration
  - 32-bit-wide level 3 (L3_MAIN) interface for command
- Supports the IDLE, STANDBY, and DISCONNECT protocols
- Asynchronous bridge (asynchronous master and slave interfaces)
- 60fps frame rate for FaceDetection processing
- Third-party IP features: For information about the input image features and detection capabilities, see Table 9-1.

PRELIMINARY

Table 9-1. Third-Party IP Features

Items	Description
Input image size	QVGA input image size H x V = 320 x 240
Input image data format	8-bit gray scale data in little-endian format (color pictures must be converted before FD can be applied) 0x00 = black and 0xFF = white
Face inclination	± 45 degrees
Face direction	Up or down: ± 30 degrees Left or right: ± 60 degrees
Maximum detection count	35 faces
Detection direction	The face orientation must be selected from the following possibilities: 0 degrees: Faces are vertical. + 90 degrees: Faces are rotated right by 90 degrees. – 90 degrees: Faces are rotated left by 90 degrees.
Detection minimum face size	Four grades are available: 20 pixels 25 pixels 32 pixels 40 pixels
Detection area	Detection start position: X = 0 to 160 Y = 0 to 120 Detection area size: X = 160 to 320 Y = 120 to 240
Detection result	The following information is provided by the module for each face: Size Position Angle Confidence level

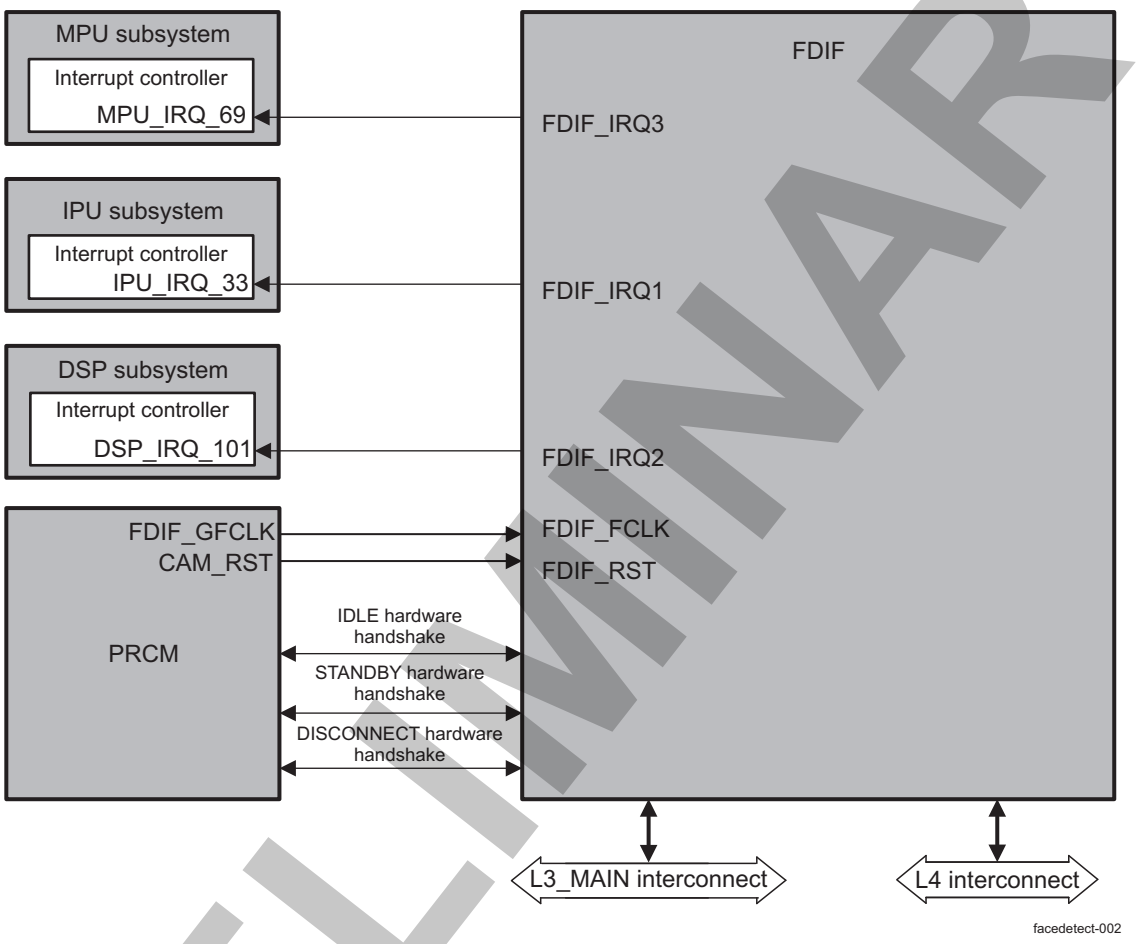
9.2 FDIF Integration

This section describes the integration of FDIF in the device, including information about clocks, resets, and hardware requests.

Figure 9-2 shows the integration of the module in the device.

Figure 9-2. FDIF Integration



NOTE: For more information about the IDLE, STANDBY, and DISCONNECT hardware handshakes, see Section 3.1.1, *Power, Reset, and Clock Management*.

Table 9-2 through Table 9-4 summarize the integration of the module in the device. For more information about the power domain or the clock and reset signals, see Section 3.1.1, *Power, Reset, and Clock Management*.

Table 9-2. Integration Attributes

9.3 FDIF Functional Description

9.3.1 FDIF Block Description

The FDIF is a stand-alone module. It has a port connected to the L4 interconnect, which is used for configuration, and a port connected to the L3_MAIN interconnect, which is used to read and write data to the system memory.

NOTE: These ports are accessible only in 32 bits.

The FD core contains the following submodules:

- FD IP core
- RAM and ROM memories

The FDIF module wraps the FD core for integration in the device. The following submodules are added:

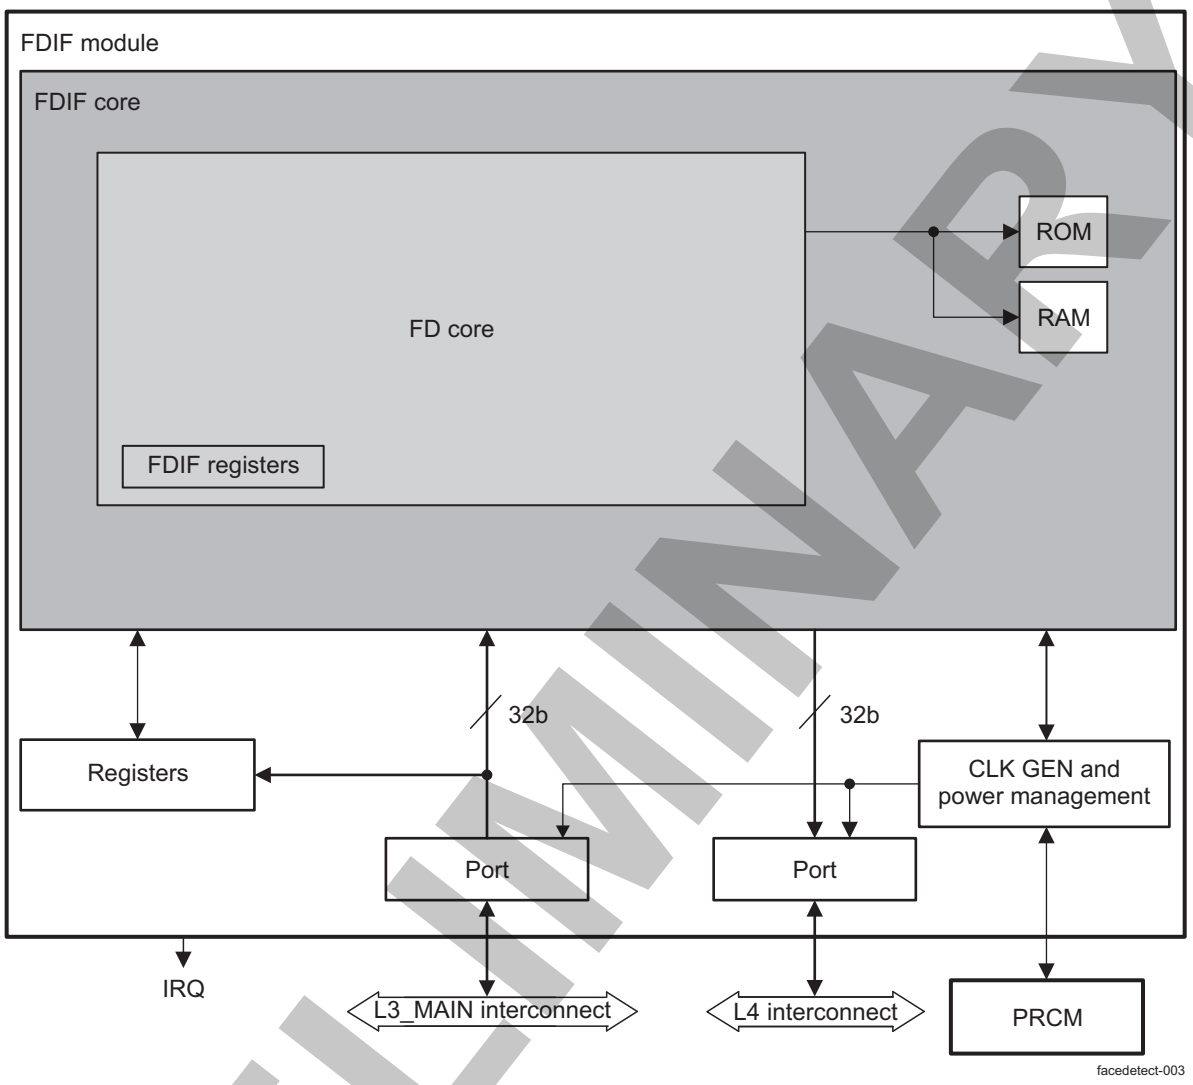
- Clock generation
- Interrupt generation
- Power management
- L3_MAIN and L4 interface ports: Two ports required to decorrelate the FDIF clocks from other system clocks, one on the L3_MAIN port interface, and one on the L4 port interface.

Figure 9-3 shows the overall architecture of the FDIF.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 9-3. FDIF Block Diagram



9.3.2 Software Reset

The module is reset by setting the FDIF_SYSCONFIG[0] SOFTRESET bit to 1. The bit is automatically reset by hardware. During reads, it always returns 0.

The FD core also provides a software reset setup by the FD_CTRL[0] SRST bit, but it is strongly recommended to use only the FDIF_SYSCONFIG[0] SOFTRESET bit.

9.3.3 System Power Management

There is one clock domain in FDIF: the L4 port domain and L3_MAIN port domain are synchronized with the module functional clock domain, FDIF_FCLK.

Table 9-5 lists the power-management features available for FDIF.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE:

- For more information about source clock gating, see Section 3.1.1, *Power, Reset, and Clock Management*.
- For descriptions of idle mode and standby mode and the power, reset, and clock management (PRCM) power handshake, see Section 3.1.1, *Power, Reset, and Clock Management*.

Table 9-5. Local Power-Management Features

Feature	Registers	Description
Clock autogating	No software control for it.	It is always enabled.
Slave idle modes	FDIF_SYSCONFIG[3:2] IDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	N/A	
Master standby modes	FDIF_SYSCONFIG[5:4] STANDBYMODE	Force-standby, no-standby, and smart-standby modes are available. For more information, see Section 9.3.3.2.1, *Protocol Transitions*.
Global wake-up enable	N/A	
Wake-up sources enable	N/A	

9.3.3.1 Autogating

The FDIF performs clock autogating whenever possible. There is no software control for the FDIF; it is always enabled.

9.3.3.2 PRCM Hardware Handshake

The FDIF supports the IDLE protocol between the L4 port and the PRCM module and the STANDBY protocol between the L3_MAIN port and the PRCM module. The FDIF also supports the DISCONNECT protocol on the L4 and L3_MAIN ports.

The FDIF first initiates the STANDBY protocol with the PRCM module, which in turn generates the IDLE protocol with the FDIF. The functional clock is gated by the PRCM module only when the IDLE and STANDBY power-management protocols are complete.

For more information about these protocols, see Section 3.1.1, *Power, Reset, and Clock Management*.

9.3.3.2.1 Protocol Transitions

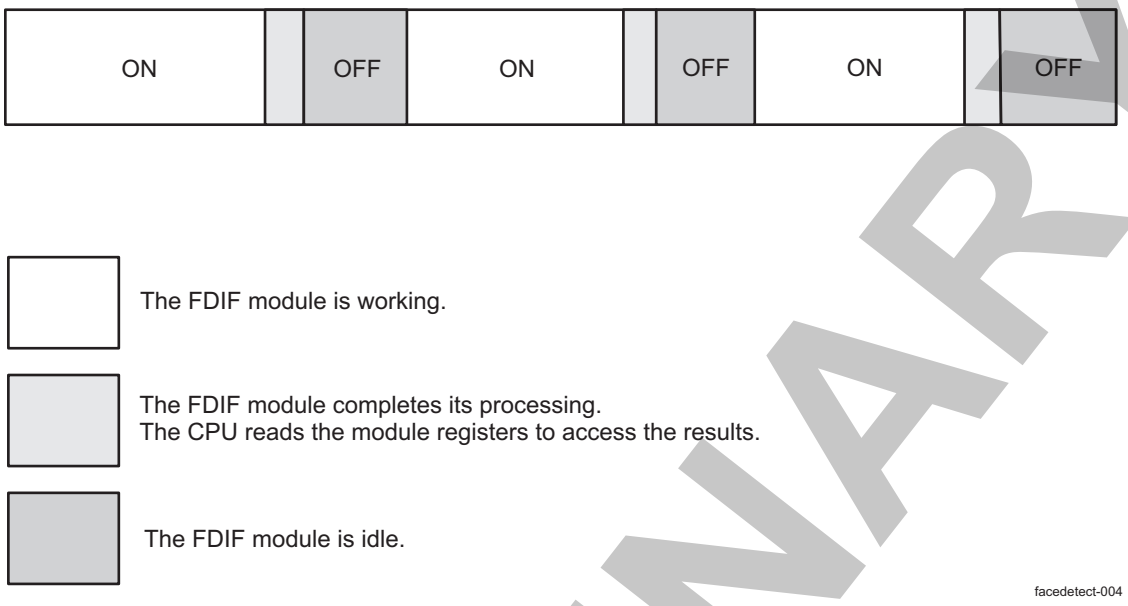
The FDIF enters the IDLE state as soon as it is done processing and the MPU has read the results of the computation.

Figure 9-4 shows the principle. The 33-ms period corresponds to a 60 fps, which is usually the target for imaging applications. Time spent in the READ state (ON state) is always the same, and the time in OFF state depends on the time spent in ON state.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 9-4. FDIF Power-Management Transitions



9.3.3.2.1.1 Normal Mode to Idle Mode

Software sets the FDIF_SYSCONFIG[5:4] STANDBYMODE bit field to 0x2 to program the power-management mode.

When its processing completes, the FD core generates the FINISH_IRQ event. At this time the FD_CTRL[1] RUN bit reflects that the FD core is idle.

Software running on the MPU reads the results of the FD algorithm. After software reads the results, it clears the FDIF_IRQSTATUS_RAW_j[8] FINISH_IRQ bit and sets the FDIF_CTRL[5] MSTANDBY bit to 1 to initiate the MStandby signal generation. For more information about the STANDBY and IDLE hardware handshakes, see Section 3.1.1, *Power, Reset, and Clock Management*.

The FDIF clock is gated only when the STANDBY and IDLE protocols are complete.

9.3.3.2.1.2 Idle Mode to Normal Mode

The PRCM module deasserts a signal to the FDIF under software control so that the module can switch back to normal mode. Then, the module functional clock is ensured and stable. Software disables the MStandby signal generation by setting the FDIF_CTRL[5] MSTANDBY bit to 0, and then polls for FDIF_CTRL[6] MSTANDBY_HDSHK = 1 to ensure that the power-management handshaking is complete. For more information about the standby and idle modes, see Section 3.1.1, *Power, Reset, and Clock Management*.

9.3.4 Interrupts and Events

The FDIF has three interrupt lines (FDIF_IRQ1, FDIF_IRQ2, and FDIF_IRQ3) to enable flexibility for controlling the module. Each event can be enabled to only a single interrupt line (that is, to only one interrupt controller [INTC]), because only one interrupt at a time can be active.

Table 9-6 lists the events the FDIF generates. The FDIF_IRQENABLE_SET_j register is used to enable an interrupt, and the FDIF_IRQENABLE_CLR_j register is used to disable an interrupt.

Table 9-6. Interrupts and Events Description

Event Name	Description
FDIF_IRQSTATUS_RAW_j / FDIF_IRQSTATUS_j[8] FINISH_IRQ	This event is generated by the FD IP core. It flags the completion of the processing by the IP.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 9-6. Interrupts and Events Description (continued)

Event Name	Description
FDIF_IRQSTATUS_RAW_j / FDIF_IRQSTATUS_j[0] OCP_ERR_IRQ	This event flags that the L3_MAIN port has received an error.

The FDIF_IRQSTATUS_RAW_j and FDIF_IRQSTATUS_j registers give the interrupt status. The difference between them is that the FDIF_IRQSTATUS_RAW_j register is set even if events are not enabled.

The FDIF_IRQSTATUS_j register can be used to clear events.

9.3.5 Typical Use

Typically, FD processing is applied to buffers provided by the ISP module, already in the correct format.

To enable FD processing, the 32-bit address of the input image in memory must be set up in the FDIF_PICADDR register, and the 32-bit address of the working memory must be set up in the FDIF_WKADDR register.

The detection condition settings can be set with the following registers:

- FD_DCOND
- FD_STARTX
- FD_STARTY
- FD_SIZEX
- FD_SIZEY

For more information, see Section 9.4, *FDIF Programming Guide*.

When the FD_CTRL[1] RUN bit is set to 1, the process starts. When the process completes (FD_CTRL[2] FINISH = 1), the results are available in the following registers:

- FD_DNUM
- FD_CENTERX_i
- FD_CENTERY_i
- FD_CONFSIZE_i
- FD_ANGLE_i

For more information, see Section 9.4, *FDIF Programming Guide*.

9.3.6 Performance Parameters

Table 9-7 lists the register settings that affect performance.

Table 9-7. Performance Parameters

Parameter	Comments
FD_DCOND[1:0] MIN	Sets the minimum face size. The permitted values are 20x20, 25x25, 32x32, and 40x40. A high value leads to higher performance.
FD_DCOND[3:2] DIR	Sets the detection direction setting. The permitted values are UP, RIGHT, and LEFT. The UP value should lead to better performance than RIGHT and LEFT.
FD_LHIT[3:0] LHIT	Sets the detection threshold. The permitted values are in the range from 0 to 9. A low value increases the FD probability detection, but it also increases false detections.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

9.3.7 Error Reporting

Interconnect protocol errors on the FDIF modules slave port are reported usin eror response. Such response is returned when non supported byte enable patterns are used to address the FD core.

Accesses to reserved or unmapped locations in the FDIF memory address range will return 0's for reads, and writes will be ignored. When the master port makes an invalid request, error is returned to the port and FDIF triggers an interrupt(OCP_ERR_IRQ, see Section 9.3.4 Interrupts and Events).

For more information about the logged errors see Section 14.2.3.9 L3_MAIN Interconnect Error Handling and Section 14.3.3.4 L4 Error Detection and Reporting.

NOTE: In case of errors, it is software responsibility to take the appropriate actions.

9.3.8 L3_MAIN Interconnect Parameters

The FDIF is an initiator on the L3_MAIN interconnect. L3 accesses can be configured with the FDIF_CTRL[4:1] MAX_TAGS bit field and the FDIF_CTRL[0] WRNP bit. For more information about these parameters, see Section 14.2.1 *L3 Interconnect*.

9.4 FDIF Programming Guide

9.4.1 FDIF Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the FDIF.

9.4.1.1 Global Initialization

9.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules the first time the FDIF is used after a device reset. This initialization of the surrounding modules is based on the integration of the FDIF. Table 9-8 describes the global initialization of surrounding modules.

For more information, see Section 9.2, *FDIF Integration*.

Table 9-8. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	FDIF_FCLK functional clock must be enabled. See Section 3.6.22, *CD_CAM Clock Domain*, in Section 3.1.1, *Power, Reset, and Clock Management*.
MPU INTC (or IPU INTC or DSP INTC)	The MPU (or IPU or DSP) INTC must be configured to enable the interrupt request generation to the MPU (or IPU or DSP) subsystem when interrupt requests are generated by the FDIF. See the respective Functional Description in Section 17.1, *Interrupt Controller*, for the MPUs Section 17.4.1, Section 17.4.2, and the DSP interrupt request lines in Section 5.1, *DSP Subsystem*, for the DSP.
Interconnect (L3 and L4)	For more information, see Section 14.2.1, *L3 Interconnect*, and Section 14.3.1, *L4 Interconnect*.

9.4.1.1.2 FDIF Global Initialization

9.4.1.1.2.1 Main Sequence – FDIF Global Initialization

Table 9-9 lists the procedure to initialize the FDIF after a poweron or software reset.

Table 9-9. FDIF Global Initialization

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	FDIF_SYSCONFIG[0] SOFTRESET	0x1
Wait until reset is finished.	FDIF_SYSCONFIG[0] SOFTRESET	0x0
Set the maximum interconnect tags.	FDIF_CTRL[4:1] OCP_MAX_TAGS	0xA
Enable ERROR type interrupt.	FDIF_IRQENABLE_SET_j[0] OCP_ERR_IRQ	0x1

RESERVED																										STANDBYMODE		IDLEMODE		RESERVED	SOFTRESET

Bits	Field Name	Description	Type	Reset
31:6	RESERVED	Reserved	R	0x0000000
5:4	STANDBYMODE	Configuration of the local initiator state management mode. By definition, initiator may generate read/write transaction as long as it is out of STANDBY state. 0x0: Force-standby mode: local initiator is unconditionally placed in standby state. Backup mode, for debug only. 0x1: No-standby mode: local initiator is unconditionally placed out of standby state. Backup mode, for debug only. 0x2: Smart-standby mode: local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. IP module shall not generate (initiator-related) wake-up events. 0x3: Reserved	RW	0x2
3:2	IDLEMODE	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, that is, regardless of the IP module's internal requirements. Backup mode, for debug only. 0x1: No-idle mode: local target never enters idle state. Backup mode, for debug only. 0x2: Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wake-up events. 0x3: Reserved	RW	0x2
1	RESERVED	Reserved	R	0
0	SOFTRESET	Software reset. Read 0x0: Reset done, no pending action Write 0x0: No action Write 0x1: Initiate software reset Read 0x1: Reset (software or other) ongoing	RW	0

Table 9-28. FDIF_CTRL

Address Offset	0x0000 0064		
Physical Address	0x4A10 A064	**Instance**	FDIF
Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																									MSTANDBY_HDSHK	MSTANDBY	OCP_MAX_TAGS				OCP_WRNP

Bits	Field Name	Description	Type	Reset
31:7	RESERVED	Reserved	R	0x0000000
6	MSTANDBY_HDSHK	MStandby / Wait power-management handshaking status bit The power-management framework of the FDIF module is based on the handshaking of the MSTANDBY and WAIT signals. When going from a idle to normal power-management transition, the software polls for FDIF_CTRL.MSTANDBY_HDSHK = 1 before starting the face detection processing. Read 0x0: Handshaking is not complete. Do not initiate traffic on L3. Read 0x1: Handshaking is complete. Can safely use the FDIF module.	R	0

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
5	MSTANDBY	MStandby signal generation. This bit shall be set to initiate a power-management transition from NORMAL to IDLE or IDLE to NORMAL. 0x0: Write: Clear MStandby signal. One polls FDIF_CTRL.MSTANDBY_HDSHK = 1 after writing this bit to ensure that the power-management handshaking is completed. 0x1: Write: Asserts MStandby signal	RW	1
4:1	OCP_MAX_TAGS	Max OCP tags. This bit field sets the maximum number of interconnect tags that the module shall use. This number is programmable between 1 (MAX_TAGS = 0) and FDIF_TAGS (MAX_TAGS = FDIF_TAGS – 1). The value of MAX_TAGS is reflected in the FIDIF_HWINFO register setting. This register setting is expected to have impact on performance. It shall be set once at initialization. Higher value gives more bandwidth to the initiator. Lower value gives less bandwidth to the initiator. This value shall be set as low as possible such that other system initiators are not penalized.	RW	0xF
0	OCP_WRNP	L3 port nonposted write control. Dynamic use of this feature is not supported. This bit shall be set at initialization and not modified hereafter until the processing completes. When nonposted writes are used, tags are used for best performance (MAX_TAGS > 1). 0x0: All writes are nonposted. 0x1: All writes are posted.	RW	0

10.1 Display Subsystem Overview

The display subsystem provides the logic to display a video frame from the memory frame buffer on a liquid-crystal display (LCD) panel or TV set.

The display subsystem can display different pictures simultaneously by using three LCD outputs (LCD1, LCD2, and LCD3), in addition to the TV output.

All three LCD outputs can use one of the following interfaces:

- Display serial interface (DSI) (MIPI® DSI)
- Remote frame buffer interface (RFBI) (MIPI DBI 2.0)
- Parallel CMOS output interface (DPI) (MIPI DPI 2.0, BT-656, or BT-1120)

NOTE: Because of device pad multiplexing, some restrictions may apply for simultaneous use of the RFBI and DP

The TV output can be one of the following:

- DPI composite signal
- High-definition multimedia interface (HDMI)

The modules integrated in the display subsystem are:

- Display controller (DISPC):
  - One direct memory access (DMA) engine
  - Three LCD outputs and one TV output, each with a dedicated overlay manager
  - One graphics pipeline (GFX), three video pipelines, and one write-back pipeline
- RFBI:
  - 8-, 9-, 12-, and 16-bit parallel interface
  - Programmable pixel memory formats
  - Programmable output formats on one or multiple cycles per pixel
- Two DSI protocol engines (DSI1_A and DSI1_C):
  - Four data-lane complex input/output (I/O) in addition to the clock lane
  - Bidirectional data link support (only one data lane is used in reverse direction in command mode)
  - Video mode and command mode support
  - Data interleaving support
- HDMI protocol engine:
  - HDMI 1.4 support at 1080p, 60 Hz (including 3D frame-packing support)
  - 36-bit RGB color
  - DES_HDCP 1.4 key protection
  - Deep color mode support (10- or 12-bit for 148.5-MHz pixel clock)

The necessary phase-locked loops (PLLs) with their control modules and the physical layers (PHYs) are outside the display subsystem. The PLLs and PHYs are paired as follows:

- DPLL_HDMI and HDMI_PHY
- DPLL_DSI1_A and DSI_PHY_DSS_A
- DPLL_DSI1_C and DSI_PHY_DSS_C

To ensure efficient bandwidth, the display subsystem integrates a connection between the level 3 (L3_MAIN) interconnect and the DISPC to exchange data with synchronous dynamic random access memory (SDRAM) and memory using the DISPC DMA engine. This connection is also used for configuration.

Figure 10-1 is a high-level diagram of the display subsystem.

NOTE: The path from a module pin to device pad (or pads) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the control module registers and dedicated IP registers. For more information, see , *Pad Functional Multiplexing and Configuration*, and , *Device Interfaces Signal Group Controls Mapping*, in Chapter 18, *Control Module*.

10.1.1.1 Display Subsystem LCD Support

LCD panels must be connected to the display subsystem of the device using parallel and/or serial interfaces.

10.1.1.1.1 Display Subsystem LCD With Parallel Interfaces

Using parallel output mode, the modules of the display subsystem path are the DISPC and RFBI or DPI.

The DISPC is connected to the memory through the L3_MAIN interconnect and uses its own DMA (with embedded FIFO) to read data from the system memory.

The remote frame buffer (RFB) of the LCD panel is connected directly to the RFBI module of the device. The RFBI controls the reads and writes to and from the RFB. The RFBI receives the output data from the DISPC and generates the signals to control the LCD panel. Through the RFBI, the microprocessor unit (MPU) can send commands or parameter and display data to the LCD panel and directly set the DISPC registers to read or write the data to and from the memory in the LCD panel.

The RFBI can be connected to all LCD outputs of the DISPC, but only one output at a time can be used. The selection (multiplexer 11 in Figure 10-2) is done through the DSS_CTRL[14] RFBI_SWITCH and DSS_CTRL[20] RFBI_SWITCH2 bit. It is not allowed to change the configuration, when the DISPC or RFBI modules are active.

For more details, see DISPC Overview, *Display Controller*, and RFBI Overview, in *Remote Frame Buffer Interface*.

In synchronous parallel interface, the required data and control signals are provided directly to an external MIPI DPI-compatible parallel panel.

All three configuration options for the LCD outputs, LCS1 to LCD3, are available, selected through the DSS_CTRL[17:16] PARALLEL_SEL bit field (multiplexer 13 in Figure 10-2):

Table 10-1 lists the outgoing display subsystem signals on the device boundary pads.

Table 10-1. Display Subsystem LCD Parallel Interface Signals Mapping

Signal Names at Device Pads (See Figure 10-2.)	DSS_CTRL[17:16] PARALLEL_SEL = 1, 2, or 3 DISPC LCDx Channel Out (pixel data, clock, syncs) (where x = 1, 2, or 3)
dispc2_fid	DISPC_LCDx_FID
dispc2_pclk	DISPC_LCDx_PCLK
dispc2_de	DISPC_LCDx_DE
dispc2_vsync	DISPC_LCDx_VSYNC
dispc2_hsync	DISPC_LCDx_HSYNC
dispc2_data[23:0]	DISPC_LCDx_DATA[23:0]

For more details on LCD output pixel data formats for the parallel interface, see DISPC Environment, in *Display Controller*.

10.1.1.1.2 Display Subsystem LCD With Serial Interfaces

In serial interface, the DISPC and the two DSI modules with their associated PLLs are used in the data path. The DISPC is connected to the memory through the L3_MAIN interconnect and uses its own DMA to read the data from the system memory.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The DSI module contains a PLL to multiply the pixel clock by an appropriate factor. The resulting serialized data is then transmitted on one to four differential data pairs and an additional clock pair that has a reference transition at the boundary between pixels.

For more details, see DSI Overview, in *MIPI Display Serial Interface*.

10.1.1.2 Display Subsystem TV Display Support

When TV data flow is needed from the display subsystem, the DPI or HDMI can be used.

10.1.1.2.1 Display Subsystem TV With Parallel Interfaces

In synchronous parallel interface, the required data is provided from the TV pipeline, and control signals are provided by the HDMI. Then they are merged and provided to the DPI.

This configurations option is available and can be selected through the DSS_CTRL[17:16] PARALLEL_SEL bit field (multiplexer 13 in Figure 10-2):

Table 10-2 lists the outgoing display subsystem signals on the device boundary pads.

Table 10-2. Display Subsystem TV Parallel Interface Signals Mapping

Signal Names at Device Pads (See Figure 10-2.)	**DSS_CTRL[17:16] PARALLEL_SEL = 0 DISPC TV Channel Out (pixel data) HDMI (pixel clock, syncs)**
dispc2_fid	HDMI_M_FID
dispc2_pclk	DSS_HDMI_PCLK
dispc2_de	HDMI_M_DE
dispc2_vsync	HDMI_M_VS
dispc2_hsync	HDMI_M_HS
dispc2_data[23:0]	DISPC_TV_DATA[29:0]

For more details on TV output pixel data formats for the parallel interface, see DISPC Environment, in *Display Controller*.

10.1.1.2.2 Display Subsystem TV With Serial Interfaces

In serial interface, the HDMI is used. The DISPC, HDMI, and DES_HDCP modules and the associated PLL modules are used in the data path. The HDMI module converts the RGB video into standard high-definition digital video format. The module has a PLL, which can multiply the pixel clock by an appropriate factor. The data is transmitted on three differential data pairs and an additional clock pair.

For more details, see HDMI Overview, in *High-Definition Multimedia Interface*.

HDMI timing clock (DSS_HDMI_TCLK) (186 MHz at OPP_NOM)	N/A	HDMI_PHY	N/A	N/A
HDMI PCLK to DISPC (DSS_HDMI_PCLK) (186 MHz at OPP_NOM)	N/A	HDMI	N/A	N/A

NOTE: For more information about the DSI1_A and DSI1_C video port clocks (VPn_PCLK and VPn_CLK, where n = 1 or 2), see Section 10.3.4.2, *DSI Clock Configuration*.

NOTE: 209.25 MHz is provided by DPLL_DSI1_A/ DPLL_DSI1_C, while frequencies provided by PRCM DPLLs have other OPP frequency restrictions. For more details, refer to the respective DPLL setting in the *Device Data Manual*.

10.1.2.2 Display Subsystem Resets

The PRCM module provides two reset signals to the display subsystem.

Figure 10-5 shows the details of the reset tree for the display subsystem.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-5. Display Subsystem Reset Scheme

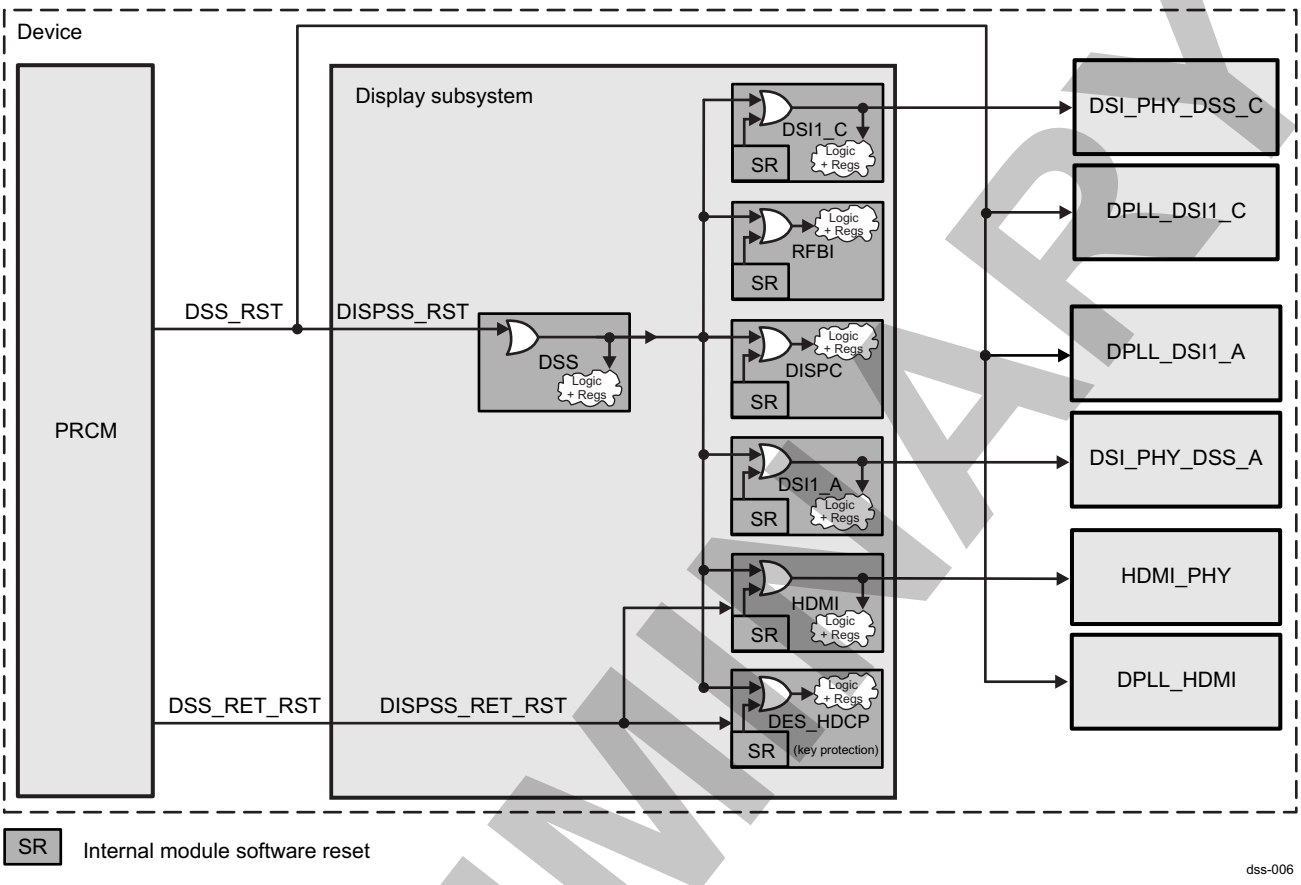

Table 10-5 lists the resets for the display subsystem.

Table 10-5. Display Subsystem Resets

Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
DSS	DISPSS_RET_RST	DSS_RET_RST	PRCM module	Retention reset
	DISPSS_RST	DSS_RST	PRCM module	Nonretention reset

The display subsystem receives its DISPSS_RST reset signal (the reset signal of the display subsystem power domain) from the PRCM module. The DISPSS_RET_RST is used only for the DES_HDCP key protection module and HDMI.

10.1.2.3 Display Subsystem Power Management

The display subsystem modules are in the display subsystem power domain.

Table 10-6 lists the power domains in the display subsystem.

Table 10-6. Display Subsystem Power Domains

Module Instance	Attributes
	Power Domain
Display subsystem	PD_DSS
DISPC	For more details, see Section 10.2.1, *DISPC Overview*.

Table 10-6. Display Subsystem Power Domains (continued)

Module Instance	Attributes
RFBI	For more details, see Section 10.5.1, *RFBI Overview*.
HDMI	For more details, see Section 10.4.1, *HDMI Overview*.

10.1.2.3.1 Display Subsystem Standby Mode

As part of the system-wide power-management scheme, the display subsystem supports the MStandby/MWait and SIdleReq/SIdleAck protocols:

- MStandby/MWait
  - DISPC
- SIdleReq/SIdleAck
  - DISPC
  - DSI1_A
  - DSI1_C
  - RFBI
  - HDMI
  - DES_HDCP (key protection)
  - DSS interconnect

The PRCM module asserts the MWait and received MStandby directly from DISPC. When the display subsystem initiates a standby procedure, it also initiates a standby/wait handshake protocol with the PRCM module that lets the PRCM module cut the display subsystem clocks. For information about the conditions that allow the subsystem to exit standby mode, see DISPC Overview, in *Display Controller*.

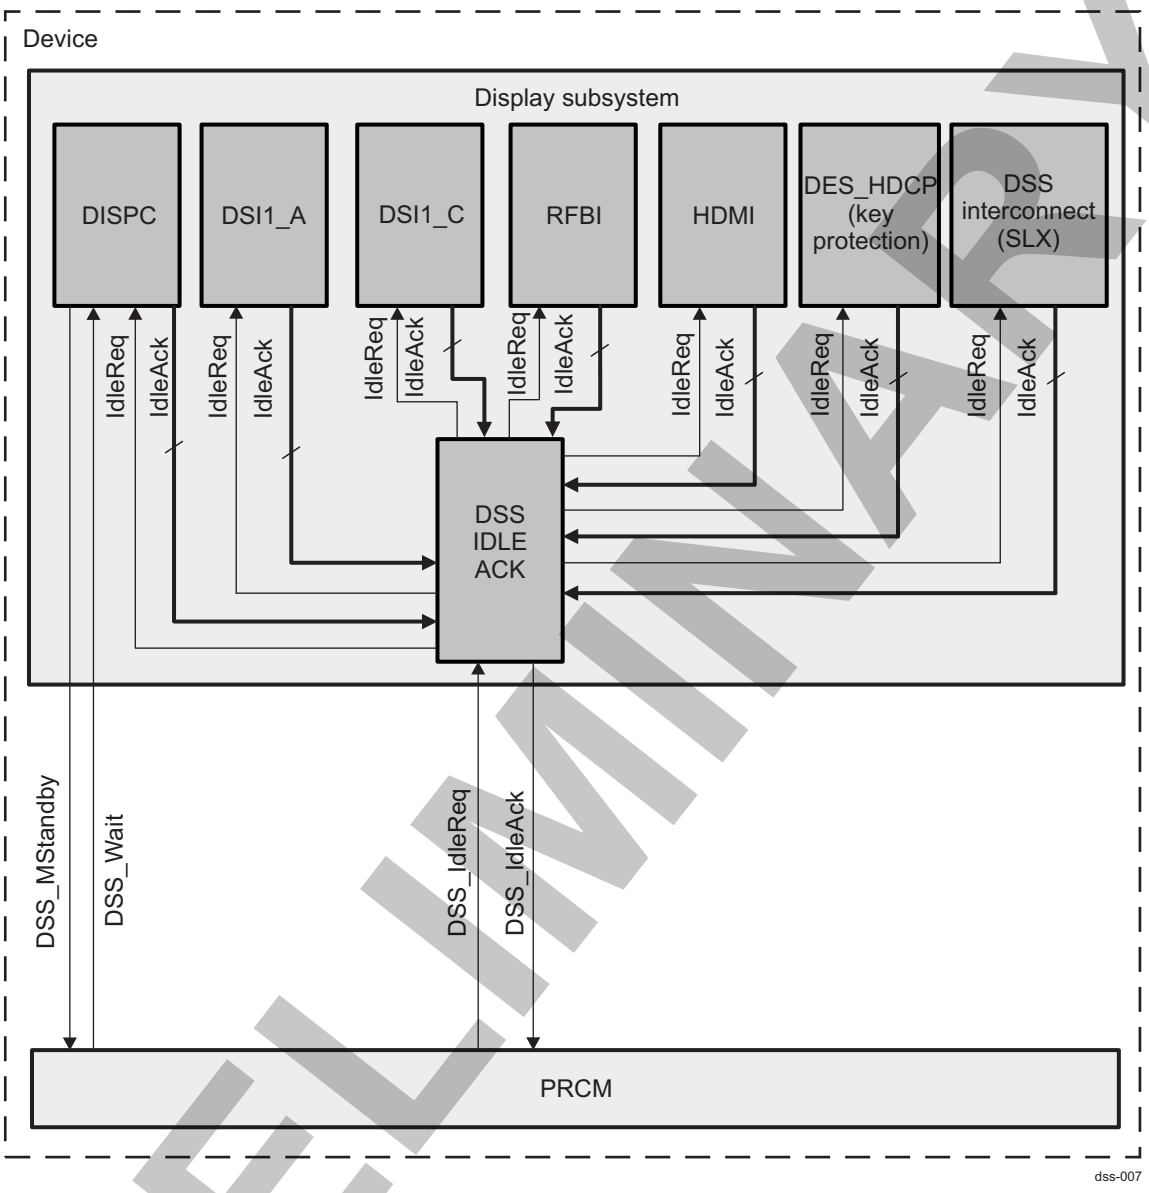
The PRCM also asserts the SIdleReq. Then, it is split at the display subsystem level and sent to the appropriate modules. Consequently, all SIdleAck are merged into one and sent back to the PRCM module.

Figure 10-6 shows the generation of SIdleAck/MStandby in the display subsystem.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-6. Display Subsystem SIdleAck/MStandby Generation



10.1.2.3.2 Display Subsystem Wake-Up Mode

The DISPC, DSI1_A, DSI1_C, and HDMI modules support the wake-up protocol. DSS_HDMI_SWakeUp is associated with DSS_HMDI_IRQ, which is generated by the HDMI module. For the events that generate an SWakeUp and the description and configuration of the registers, see the DISPC, DSI, and HDMI TRM chapters.

Figure 10-7 shows wake-up generation in the display subsystem.

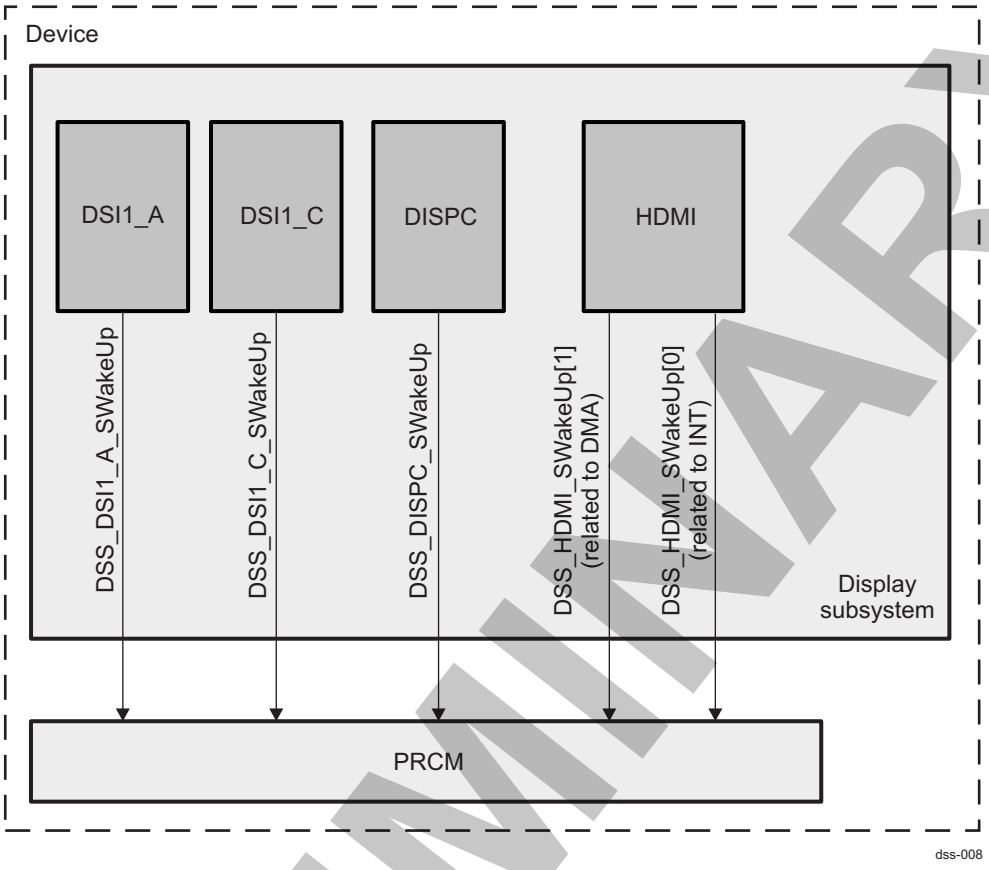
Figure 10-7. Display Subsystem Wake-Up Generation



10.1.2.4 Display Subsystem Interrupt Requests

The display subsystem has four interrupt lines. The interrupt signals are connected to the MPUs and digital signal processor (DSP) interrupt controller (INTC) modules. The interrupts are generated from the DISPC, DSI1_A, DSI1_C, and HDMI.

Figure 10-8 shows interrupt generation in the display subsystem.

10.1.2.5 Display Subsystem DMA Requests

Eleven DMA requests are connected to the DMA_SYSTEM.

The DMA_SYSTEM requests are:

- Four DMA request signals from each DSI protocol engine (data traffic: from SDRAM or IVA-HD SL2 to DSI protocol engine and from DSI protocol engine to SDRAM or IVA-HD SL2)
- One DMA request signal from RFBI module (data traffic: from SDRAM to RFBI)
- One DMA request signal from HDMI module (audio traffic: from SDRAM or IVA-HD SL2 to HDMI)
- One DMA request signal from DISPC module (used for synchronization of a logical channel in the DMA_SYSTEM for memory-to-memory transfers)

Figure 10-9 shows the details of DMA request generation in the display subsystem.

Figure 10-9. Display Subsystem DMA Request Generation

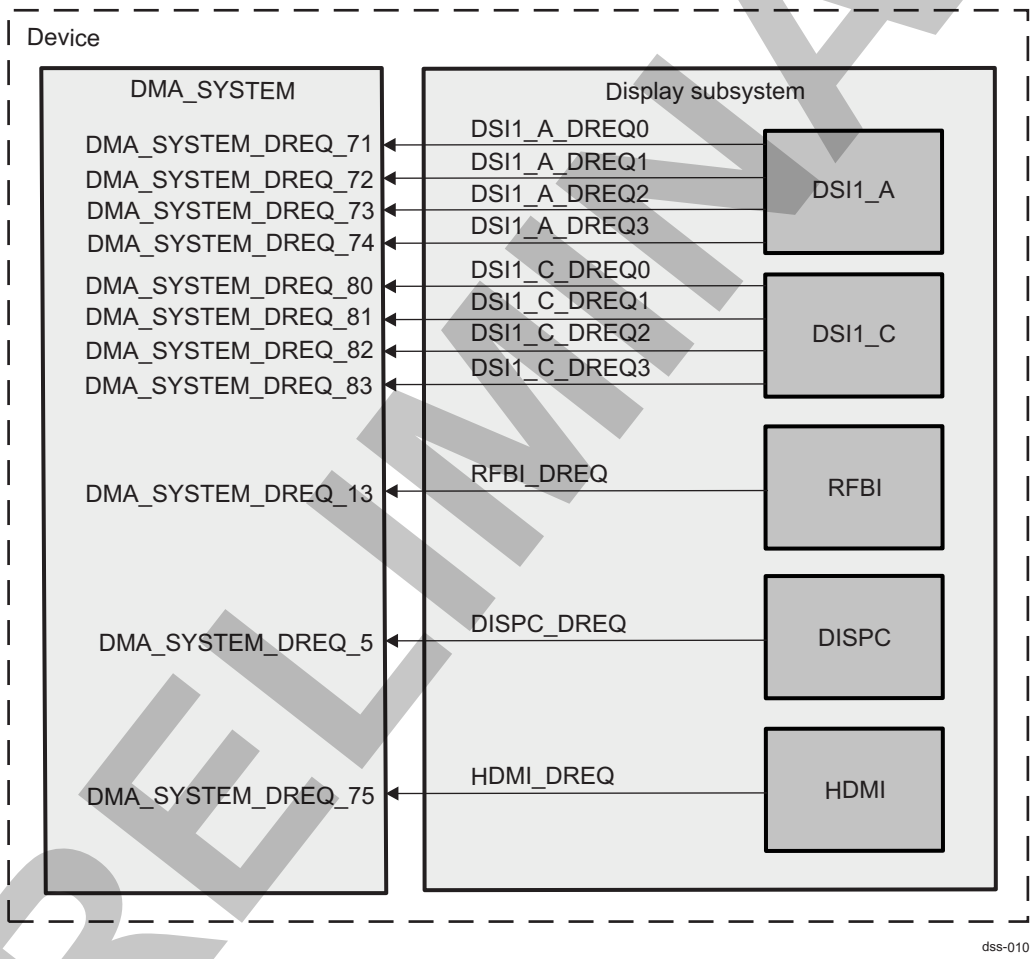

Table 10-8 lists the display subsystem DMA_SYSTEM requests.

Table 10-8. Display Subsystem DMA_SYSTEM Requests

DMA_SYSTEM Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**

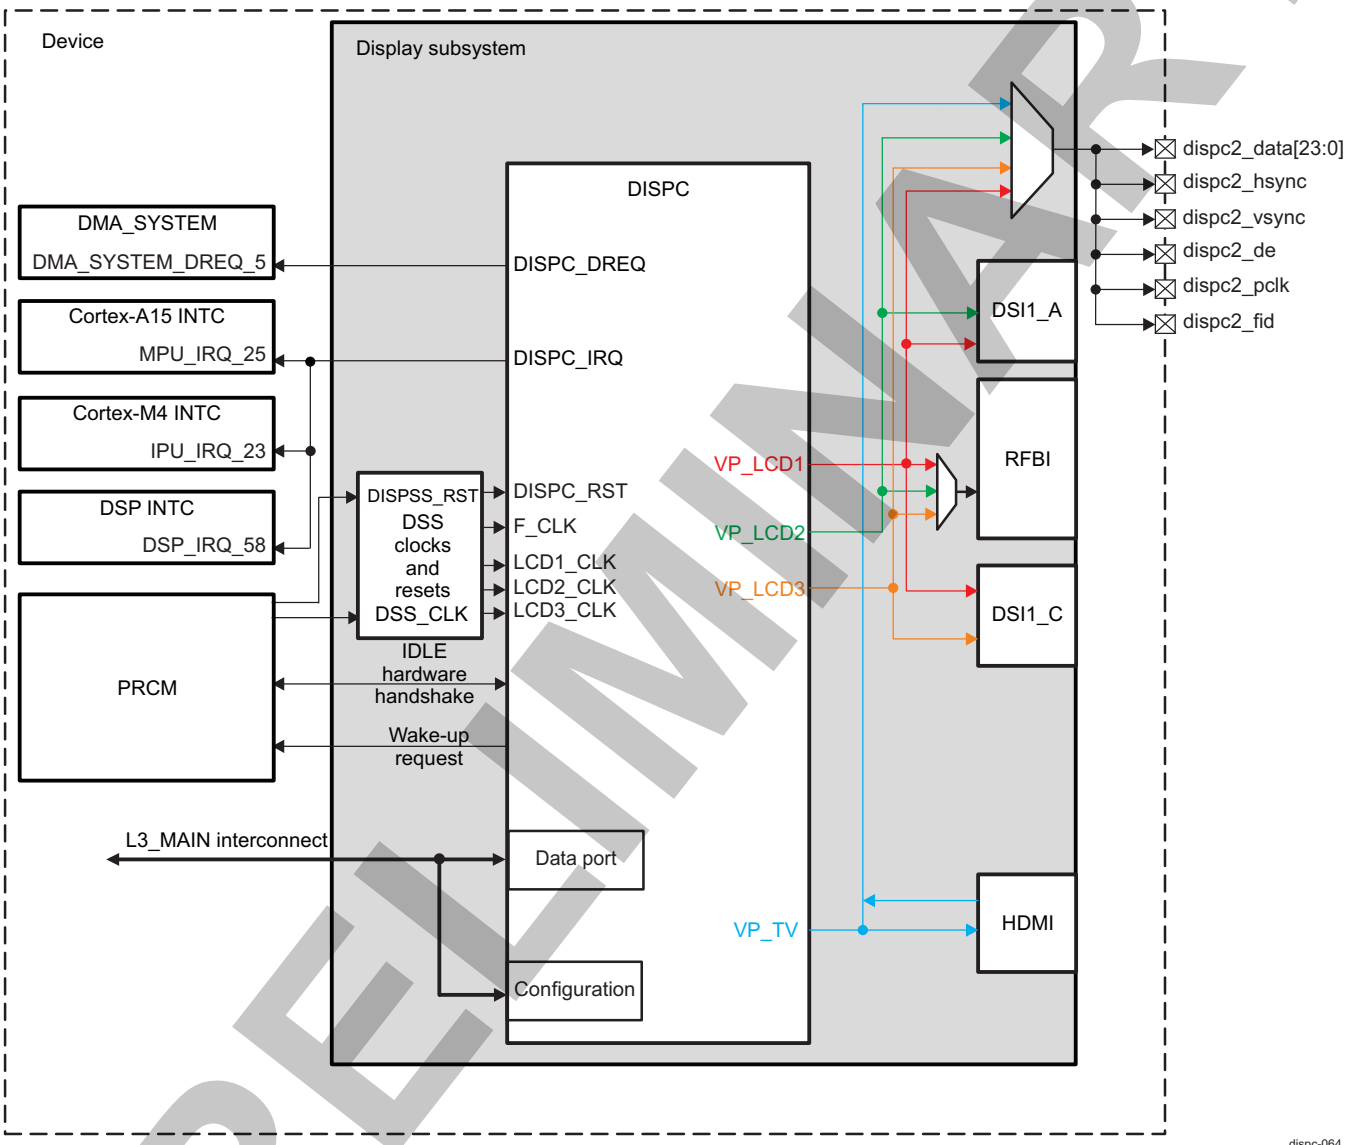
10.2 Display Controller

10.2.1 DISPC Overview

Figure 10-10 shows a block diagram of the display controller (DISPC) within the display subsystem.

Figure 10-10. DISPC Overview



The DISPC includes the following main features:

- Five pipelines for processing:
  - One GFX:
    - Pixel formats: ARGB16-4444, xRGB12-4444, RGBA16-4444, RGBx12-4444, RGB16-565, ARGB16-1555, xRGB16-1555, ARGB32-8888, RGBA32-8888, xRGB32-8888, RGBx32-8888, xRGB24-8888, RGBx24-8888, BGRA32-8888, RGB24-888 (packed), and BITMAP (1 2, 4, or 8 bits per pixel) (where x means that the corresponding bits in the container are not used)
    - Premultiplied ARGB and RGBA formats
    - Selection of the color depth expansion from ARGB16-4444, RGBA16-4444, and ARGB16-1555 to ARGB32-8888, and from xRGB12-4444, RGBx12-4444, and xRGB16-1555 to xRGB32-8888 (replication of the most significant bits [MSBs] or adding 0s)

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- Support for color look-up table (CLUT): 256 × 24-bit entries palette in RGB
- Support for antiflicker on RGB pixel formats using 3-tap filter

– Three video pipelines (VID1, VID2, and VID3):
  - Pixel formats: ARGB16-4444, xRGB12-4444, RGBx12-4444, RGBA12-3333, RGBA16-4444, RGB16-565, ARGB16-1555, xRGB16-1555, ARGB32-8888, RGBA32-8888, xRGB32-8888, RGBx32-8888, RGB24-888, BGRA32-8888, YUV4:2:2-UYVY, YUV4:2:2-YUV2, YUV4:2:0-NV12, and YUV4:2:0-NV21 (where x means that the corresponding bits in the container are not used)
  - Premultiplied ARGB and RGBA formats
  - Selection of the color depth expansion from ARGB16-4444, RGBA16-4444, and ARGB16-1555 to ARGB32-8888, and from xRGB12-4444, RGBx12-4444, and xRGB16-1555 to xRGB32-8888 (replication of the MSBs or adding 0s)
  - Programmable poly-phase filter:
    - Independent horizontal and vertical resampling: Upsampling (up to x8) and downsampling (down to 1/4)
    - Maximum input width of 1920 pixels
    - No limitation on the input height
    - Supported input formats are ARGB32-8888, YUV4:2:2-UYVY, YUV4:2:2-YUV2, YUV4:2:0-NV12, and YUV4:2:0-NV21
    - Alpha blending factor is rescaled like the R, G, and B color components.
  - Programmable color space conversion from YUV4:2:2 (YUV4:4:4, YUV4:2:0 after Chroma upsampling through the scaler) into ARGB32-8888. Images in YUV4:2:2 format with 90- or 270-degree rotation are preprocessed to YUV4:4:4 before the scaler, by duplicating the missing Chroma.
  - Programmable VC-1 range mapping

– One write-back (WB) pipeline: Allows the use of the hardware processing available inside the DISPC, such as color space conversion, rescaling, and compositing to perform memory-to-memory transfer with data processing or capturing a displayed frame
  - Programmable color space conversion RGB24 into YUV4:4:4 or to YUV4:2:2-UYVY, YUV4:2:2-YUV2, YUV4:2:0-NV12, or YUV4:2:0-NV21 using programmable poly-phase filter
  - Programmable color space conversion RGB24 into YUV4:2:2-UYVY, YUV4:2:2-YUV2, YUV4:2:0-NV12, or YUV4:2:0-NV21
  - Selection of the color depth reduction from RGB24 to RGB16
  - Programmable poly-phase filter:
    - Independent horizontal and vertical resampling: Upsampling (up to x8) and downsampling (down to 1/4)
    - Maximum input width of 1920 pixels
    - No limitation on the input height
    - Supported input formats are ARGB32-8888, YUV4:2:2-UYVY, YUV4:2:2-YUV2, YUV4:2:0-NV12, and YUV4:2:0-NV21
    - Alpha blending factor is rescaled like the R, G, and B color components.
  - Selection of the source of the data:
    - Overlay output:
      - Primary LCD output
      - Secondary LCD output
      - Third LCD output
      - TV output
    - Pipelines:
      - Graphic
      - Video 1

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

    - Video 2
    - Video 3
- Three LCD outputs: primary (LCD1), secondary (LCD2), and tertiary (LCD3):
  - Input pixel format: ARGB32-8888
  - Output pixel format: RGB24-888 and YUV4:2:2 (YUV4:2:2 only available when Bluetooth mode output is enabled)
  - Overlay of graphic and video for one to four pipelines
  - Source and destination transparency color key
  - Global and pixel alpha blending (up to 8-bit blending factor)
  - Z-order programmable (full flexibility)
  - Displays supported:
    - Active matrix color: 12-, 16-, 18-, and 24-bit panel interface support (replicated or dithered encoded pixel values)
  - Independent programmable timing generators for LCD1, LCD2, and LCD3 to support:

Using DSI1_A interface	WUXGA (1920x1200) @ 60 fps with 24 bpp (VESA timing)
Using RFBI	WVGA @ 30 fps
Using DSI1_C interface	WUXGA (1920x1200) @ 60 fps with 24 bpp (VESA timing)
Using CMOS interface	SXGA VESA timing @ 60 fps, 1080i/720p @ 60 fps CEA-861-D, UXGA @ 60 fps

  - Configurable LCD output mode: progressive or interlace mode
  - Remote frame buffer support through the RFBI module
  - Partial display through the RFBI
  - Multiple-cycle output format on 8-, 9-, 12-, and 16-bit interface time division multiplexing (TDM)
- One TV output:
  - Input pixel format: ARGB40-10.10.10.10
  - Output pixel format: ARGB40-10.10.10.10
  - Overlay of graphic and video for one to four pipelines
  - Source and destination transparency color key
  - Global and pixel alpha blending (up to 10-bit blending factor)
  - Z-order programmable (full flexibility)
  - Slave mode support (no master mode support) with synchronization signals provided by HDMI TX:
    - HSYNC (horizontal synchronization signal)
    - VSYNC (vertical synchronization signal)
    - RE (data request signal)
    - FID (field ID: even and odd field information)
  - RGB30-10.10.10 data bus output for connection to HDMI TX and extended to 36 by duplication of the MSBs
  - HD-1080p, HD-1080i, HD-720p, SD-480p, SD-576p, SD-576i, and SD-480i using HDMI
  - HDMI deep color mode support, 30-bit data output to HDMI encoder
  - Pixel duplication capability (from one pixel clock cycle up to eight cycles)
- Panel support with MIPI DPI protocol:
  - 12-, 16-, 18-, and 24-bit active matrix panel interface support (replicated or dithered encoded pixel values)
- Common:
  - Rotation 0, 90, 180, and 270 degrees using DMM-TILER
  - Synchronized buffer update

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

  - Hardware cursor (using the graphics pipeline or one of the video pipelines)
  - Independent gamma curve support on LCDs outputs and TV output
  - Multiple-buffer support
  - Mirroring/flip-flop support (using DMM-TILER)
  - Programmable color phase rotation (CPR)
  - Alpha blending support:
    - Embedded pixel factor (ARGB and RGBA)
    - Global alpha
- DMA (internal to the DISPC):
  - Support for accessing tiled structure through the TILER inside the dynamic memory management (DMM)
  - Support for accessing nontiled structure through the TILER or directly
  - Support for rotation, flip-flop, and mirroring though the TILER inside the DMM
  - Support for memory fragmentation though the TILER inside the DMM
  - Integrated shared buffers between DMA engine and pipelines
  - Programmable buffer thresholds
  - Bandwidth limiter on write request (insertion on idle cycles between requests)
- Advanced:
  - Mode outputting data on display only from the DMA buffer (self-refresh using the DMA FIFO)
  - DMA buffer hand-check in stall mode
  - Arbitration between high and low priority (GFX, VID1, VID2, VID3, and WB pipelines)
- Power modes:
  - Low-power saving modes
  - Support on-the-fly dynamic voltage and frequency scaling (DVFS)
  - Merge capability of the DMA buffers to support greater OFF period on the L3_MAIN interconnect
    - All buffers associated to a single pipeline
    - Reallocation of the buffers of the nonactive pipelines to the active pipelines

10.2.2 DISPC Environment

The DISPC provides the required control signals to interface directly to an external parallel panel for the MIPI DPI protocol.

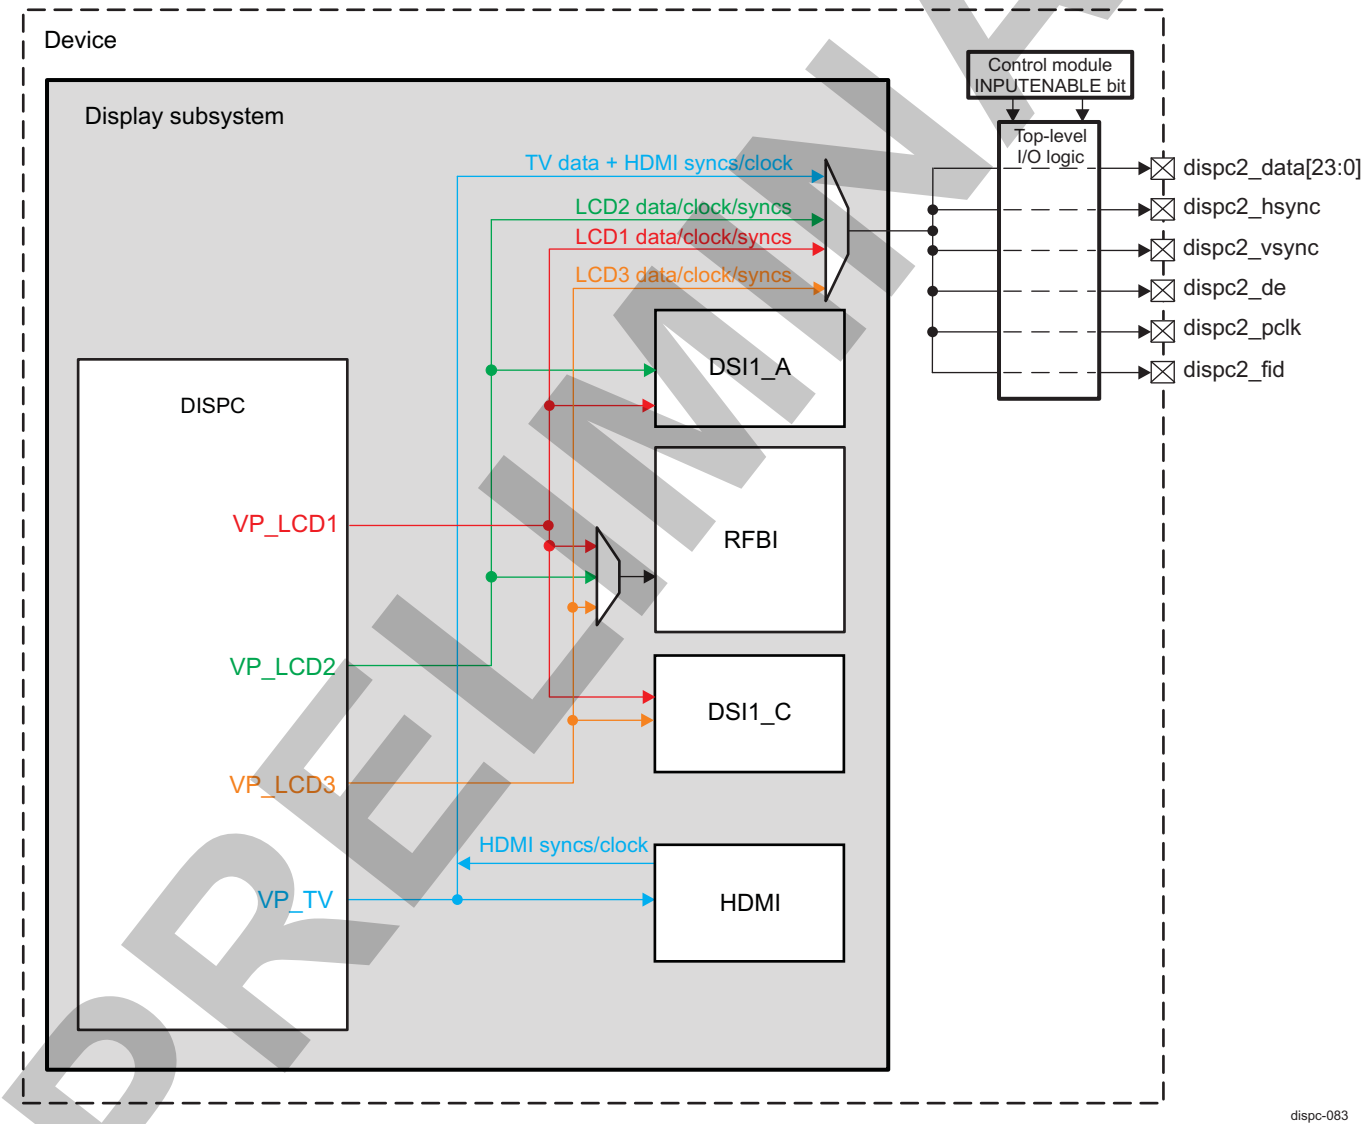
Figure 10-11 shows the LCD support parallel interface.

NOTE: Parallel interface is available through the LCD1, LCD2, LCD3, and TV outputs of the DISPC.

The LCD data and control signals are multiplexed with the TV output data, and control signals are provided by the HDMI module.

The selection can be done at the top level of the display subsystem. For further details and signal mapping, see Section 10.1.1, *Display Subsystem Environment*.

Figure 10-11. DISPC LCD Support Parallel Interface



PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: The path from a module pin to device pad (or pads) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the control module registers and dedicated IP registers. For more information, see , *Pad Functional Multiplexing and Configuration*, and , *Device Interfaces Signal Group Controls Mapping*, in Chapter 18, *Control Module*.

Table 10-19 describes the interface signals to/from the LCD panel in bypass mode.

Table 10-19. DISPC Parallel Interface Signals

Signal Name	Type[1]	Description
dispc2_data[23:0]	O	Pixel data
dispc2_pclk	O	Pixel clock
dispc2_vsync	O	Vertical synchronization. The LCD frame clock (vsync) toggles after all the lines in a frame are transmitted to the LCD panel and a programmable number of line clock cycles has elapsed at the beginning and end of each frame.
dispc2_hsync	O	Horizontal synchronization. The LCD line clock (hsync) toggles after all pixels in a line are transmitted to the LCD panel and a programmable number of pixel clock wait-states has elapsed at the beginning and end of each line.
dispc2_de	O	In active matrix technology, the DE signal acts as an output-enable signal to indicate when data must be latched using the pixel clock.
dispc2_fid	O	The FID signal indicates the field identifier for the LCD output field: • 0 means even. • 1 means odd.

(1) I = Input, O = Output, I/O = Input/Output

10.2.2.1 DISPC LCD Output and Data Format for the Parallel Interface

This section describes the pixel data bus and shows timing diagrams of transactions and synchronizations.

Figure 10-12 through Figure 10-15 show the pixel data bus, depending on the use of 4-, 8-, 12-, 16-, 18-, or 24-pixel data output pins.

In the Active matrix display type, one pixel per pixel clock is displayed.

Active matrix technology:

Active matrix displays bypass the STN dithering logic block and the output FIFO. Each line represents one pixel.

Figure 10-12 through Figure 10-15 show 12-, 16-, 18-, and 24-active matrix displays, respectively.

10.2.2.2 DISPC Transaction Timing Diagrams

Figure 10-16 through Figure 10-19 show timing diagrams of synchronization signals and pixel clocks for active matrix panels. The DISPC directly drives these signals, which are related to the programmable fields listed in Table 10-20.

Table 10-20. DISPC Programmable Fields in Bypass Mode

Name	Register	Description
PPL	DISPC_SIZE_LCDo[11:0] PPL value + 1	Pixels per line
LPP	DISPC_SIZE_LCDo[27:16] LPP value + 1	Lines per panel
HBP	DISPC_TIMING_Ho[31:20] HBP value + 1	Horizontal back porch
HFP	DISPC_TIMING_Ho[19:8] HFP value + 1	Horizontal front porch
HSW	DISPC_TIMING_Ho[7:0] HSW value + 1	Horizontal synchronization pulse width
VBP	DISPC_TIMING_Vo[31:20] VBP value	Vertical back porch
VFP	DISPC_TIMING_Vo[19:8] VFP value	Vertical front porch
VSW	DISPC_TIMING_Vo[7:0] VSW value + 1	Vertical synchronization pulse width
ONOFF	DISPC_POL_FREQo[17] ONOFF	DISPC_HSYNC and DISPC_VSYNC pixel clock control
RF	DISPC_POL_FREQo[16] RF	DISPC_HSYNC and DISPC_VSYNC pixel clock edge control
IEO	DISPC_POL_FREQo[15] IEO	Invert DISPC_ACBIAS
IPC	DISPC_POL_FREQo[14] IPC	Invert DISPC_PCLK
IHS	DISPC_POL_FREQo[13] IHS	Invert DISPC_HSYNC
IVS	DISPC_POL_FREQo[12] IVS	Invert DISPC_VSYNC

- Active matrix timing configuration 1:
  - DISPC_POL_FREQo[17] ONOFF = 0
  - DISPC_POL_FREQo[16] RF = 0

10.2.2.3 DISPC TV Output and Data Format for the Parallel Interface

This section describes the TV output pixel data bus for the parallel interface.

The TV pixel data interface is a 30-bit RGB interface. Only the MSB part of each color component is connected to the display subsystem boundary: R[9:2], G[9:2], B[9:2]. The output of the data is synchronized to the data request signal (HDMI_M_DE) from the HDMI encoder.

Figure 10-28 shows the format of the TV output pixel data.

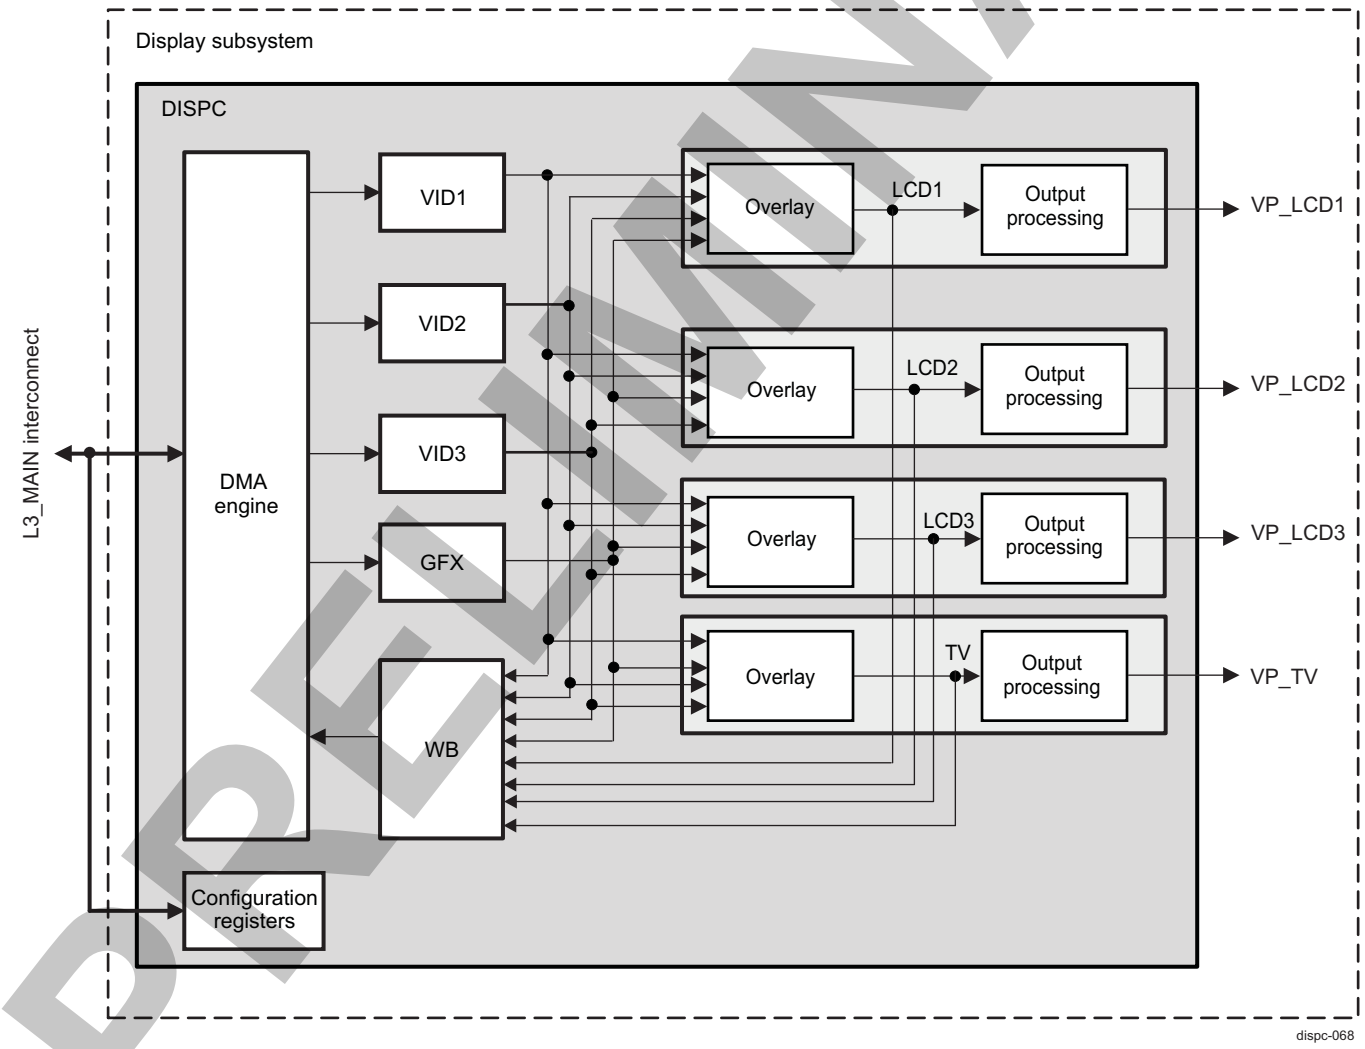
10.2.4 DISPC Functional Description

The DISPC can read and display the encoded pixel data stored in memory (see Figure 10-30).

Figure 10-30. DISPC Architecture Overview



The DISPC can read and display the encoded pixel data stored in memory and write the output of one of the overlays or one of the pipelines into system memory.

Several processes can be configured to manage the graphics pipeline (palette, antiflicker) and video pipelines (VC-1, color space conversion, scaling, overlay, transparency, and so forth).

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The data coming out of a pipeline is sent to one of the four outputs, depending on the user configuration. An overlay manager manages inputs of multiple pipelines. User timing configurations for LCD and TV are available.

The DISPC allows the capturing of one output of the pipeline or overlay manager to redirect it into the WB pipeline. It allows the use of the hardware processing available inside the DISPC, such as color space conversion, rescaling, and compositing, and so forth to perform memory-to-memory transfer with data processing.

10.2.4.1 DISPC Clock Configuration

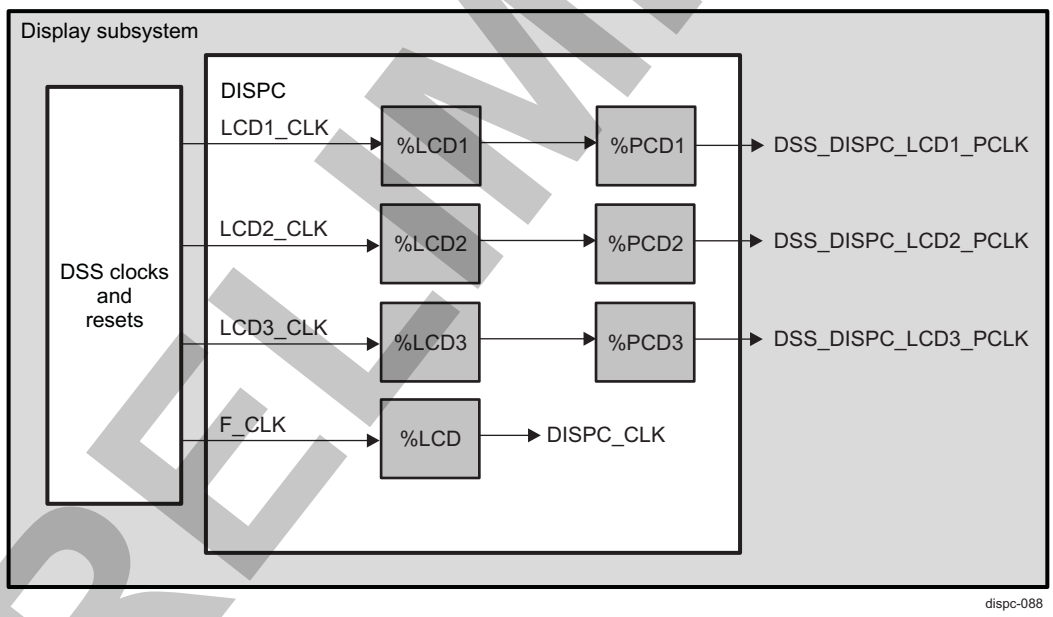
The PCLK frequency for each LCD output is derived from a dedicated input clock: LCD1_CLK, LCD2_CLK, or LCD3_CLK for the three LCD outputs, respectively. Each input clock is divided by the values of the DISPC_DIVISORo[23:16] LCD bit field and then the DISPC_DIVISORo[7:0] PCD bit field independently for each LCD pixel clock (see Figure 10-31). DSS_DISPC_LCD1_PCLK, DSS_DISPC_LCD2_PCLK, and DSS_DISPC_LCD3_PCLK are independent:

- DSS_DISPC_LCD1_PCLK = (LCD1_CLK/LCD1) / PCD1
- DSS_DISPC_LCD2_PCLK = (LCD2_CLK/LCD2) / PCD2
- DSS_DISPC_LCD3_PCLK = (LCD3_CLK/LCD3) / PCD3

The functional clock of the DISPC is derived from F_CLK by an independent divisor. The dividing value is set in the DISPC_DIVISORo[23:16] LCD bit field.

For backward compatibility, the divisor value LCD can be set to the value of LCD1. To enable this functionality, the DISPC_DIVISOR[0] ENABLE bit must be set to 1.

Figure 10-31. DISPC Clock Tree Overview



10.2.4.2 DISPC Software Reset

To perform a software reset on the DISPC, set the DISPC_SYSCONFIG[1] SOFTRESET bit to 0x1. The DISPC_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 0x1. When the software reset completes, the DISPC_SYSCONFIG[1] SOFTRESET bit is automatically reset. Software must ensure that the software reset completes before performing DISPC operations.

10.2.4.3 DISPC Power Management

The DISPC supports the MStandby/Wait, IdleReq/SidleAck, and wake-up protocols as defined in Chapter 3, *Power, Reset, and Clock Management*.

Copyright © 2013, Texas Instruments Incorporated
PRELIMINARY

10.2.4.3.1 DISPC Idle Mode

The DISPC supports no-idle mode, force-idle mode, and smart-idle mode. The mode can be selected by programming the appropriate value in the DISPC_SYSCONFIG[4:3] SIDLEMODE bit field.

Condition of assertion of the SIdleAck signal:

- In no-idle mode: SIdleAck is never asserted.
- In force-idle mode: SIdleAck is asserted unconditionally with a 1-configuration port interface clock cycle delay with respect to an IdleReq assertion.

NOTE: The proper use of force-idle mode assumes that no interrupt needs to be generated.

- In smart-idle mode: SIdleAck is asserted when at least the following conditions are satisfied:
  - No interrupt is pending.
  - The DISPC no longer uses the interface clock for the slave port.

Once SIdleAck is asserted, the DISPC interface lock used by the slave port can be shut down at any time.

The conditions of deassertion of the SIdleAck signal are:

- In force-idle mode: SIdleAck is deasserted with a 1-configuration port interface clock cycle delay with respect to an IdleReq deassertion.
- In smart-idle mode: SIdleAck is deasserted with a 1-configuration port interface clock cycle delay with respect to an IdleReq deassertion.

Once SIdleAck is released, the DISPC is fully operational and a DMA request can be processed normally.

10.2.4.3.2 DISPC StandBy Mode

The DISPC supports no-standby mode, force-standby mode, and a single smart-standby mode. The mode is set in the DISPC_SYSCONFIG[13:12] MIDLEMODE bit field. The functional clock is always active if the module is enabled. The L3_MAIN clock can be shut down at any time independently of the status of MStandby.

The conditions of assertion of the MStandby signal are:

- In no-standby mode: MStandby is never asserted.
- In force-standby mode: MStandby is asserted when the module is disabled.
- In smart-standby: In the case of one of the following conditions:
  - The GFX pipeline is disabled or enabled and the data fetch is complete for the GFX window, or the GFX pipeline is enabled but the data fetch did not complete and data in the DMA buffer is greater than the high threshold value.
  - The VID1 pipeline is disabled or enabled and the data fetch is complete for the VID1 window, or the VID1 pipeline is enabled but the data fetch did not complete and data in the DMA buffer is greater than the high threshold value.
  - The VID2 pipeline is disabled or enabled and the data fetch is complete for the VID2 window, or the VID2 pipeline is enabled but the data fetch did not complete and data in the DMA buffer is greater than the high threshold value.
  - The VID3 pipeline is disabled or enabled and the data fetch is complete for the VID3 window, or the VID3 pipeline is enabled but the data fetch did not complete and data in the DMA buffer is greater than the high threshold value.
  - The WB pipeline is disabled or enabled and the data store to memory is complete for the WB picture, or the WB pipeline is enabled but the data storage did not complete and data in the DMA buffer is lower than the low threshold value.

The MStandby signal asserts whenever all five events have occurred or the DISPC is disabled. While MStandby is asserted, the DISPC does not generate any transaction on the L3_MAIN master port.

The conditions of deassertion of the MStandby signal are:

- In force-standby mode: MStandby is deasserted only when the DISPC is enabled.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- In smart-standby mode: In the case of one of the following conditions:
  - The GFX pipeline is enabled but the data fetch did not complete for the GFX window, and the data in the DMA buffer is less than the low threshold value.
  - The VID1 pipeline is enabled but the data fetch did not complete for the VID1 window, and the data in the DMA buffer is less than the low threshold value.
  - The VID2 pipeline is enabled but the data fetch did not complete for the VID2 window, and the data in the DMA buffer is less than the low threshold value.
  - The VID3 pipeline is enabled but the data fetch did not complete for the VID3 window, and the data in the DMA buffer is less than the low threshold value.
  - The WB pipeline is enabled but the data store did not complete for the WB picture, and the data in the DMA buffer more than the high threshold value.

Detection of the deassertion conditions assumes that the interface clocks are active.

10.2.4.3.3 DISPC Wakeup

The DISPC supports wake-up signaling. The mode can be selected by programming the appropriate value in the DISPC_SYSCONFIG[2] ENAWAKEUP bit. Because the SWakeUp signal is asynchronous, it does not require the interface clock.

The conditions of assertion of the SWakeUp signal are:

- The GFX pipeline is enabled but the data fetch did not complete for the GFX window, and the data in the DMA buffer is less than the low threshold value.
- The VID1 pipeline is enabled but the data fetch did not complete for the VID1 window, and the data in the DMA buffer is less than the low threshold value.
- The VID2 pipeline is enabled but the data fetch did not complete for the VID2 window, and the data in the DMA buffer is less than the low threshold value.
- The VID3 pipeline is enabled but the data fetch did not complete for the VID3 window, and the data in the DMA buffer is less than the low threshold value.
- The WB pipeline is enabled and the data in the DMA buffer is more than the high threshold value.
- The last pixel displayed into the LCD1 panel if it is not the last frame
- The last pixel displayed into the LCD2 panel if it is not the last frame
- The last pixel displayed into the LCD3 panel if it is not the last frame
- The last pixel displayed into the TV panel if it is not the last frame

The SWakeUp signal is asserted whenever any one of these nine events occurs and IdleAck is asserted.

When one of the active pipelines reaches the low threshold and must refill its DMA buffer for the current frame, all other pipelines refill their own DMA buffer even if their low threshold has not been reached. The DISPC_CONFIG1[17] BUFFERFILLING bit is used to increase the probability that the time increases, where there is no access to the L3_MAIN interconnect.

The condition of deassertion of the SWakeUp signal is:

- Immediately after deassertion of IdleReq

10.2.4.4 DISPC Interrupt Requests

The interrupt line, DISPC_DREQ, indicates when one or more events are detected by the hardware. Each event is independently maskable by setting the DISPC_IRQENABLE register.

To check when a particular interrupt event occurs and to reset a particular event, the DISPC_IRQSTATUS register must be accessed. This register regroups the status of internal events in the module that generate an interrupt (read 0: no interrupt occurred; read 1: interrupt occurred; write 1: status bit reset). For more information about checking and clearing interrupt events, see Section 10.1.3, *Display Subsystem Register Manual*.

Table 10-24 describes the interrupts generated for the DISPC.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 10-24. DISPC Interrupts

Interrupt Name	Description
FLIPIMMEDIATEDONE_IRQ	Flip immediate done: Occurs when the DMA engine has acknowledged the immediate BA change, and software can write the new BA0.
FRAMEDONE1_IRQ	Frame done for LCD1 output: Active frame related to the LCD1 is complete and LCD1 output of the DISPC is disabled.
FRAMEDONE2_IRQ	Framedone for LCD2 output: Active frame related to the LCD2 is complete and LCD2 output of the DISPC is disabled.
FRAMEDONE3_IRQ	Frame done for LCD3 output: Active frame related to the LCD3 is complete and LCD3 output of the DISPC is disabled.
FRAMEDONETV_IRQ	Frame done for TV output: Active frame related to the TV output is complete and TV output of the DISPC is disabled.
FRAMEDONEWB_IRQ	Frame done for WB output: Active frame related to the WB is complete. First, it is used when the WB channel is connected to one of the pipelines to determine when the memory-to-memory transfer through DISPC is completed. Second, it is used when the WB channel is connected to one of the overlay output in nonreal-time mode to determine when the memory-to-memory transfer with overlay processing is completed.
VSYNC1_IRQ	VSYNC for primary LCD output: VSYNC interrupt for the primary LCD has occurred at the end of the frame.
VSYNC2_IRQ	VSYNC for secondary LCD output: VSYNC interrupt for the secondary LCD has occurred at the end of the frame.
VSYNC3_IRQ	VSYNC for third LCD output: VSYNC interrupt for the third LCD has occurred at the end of the frame.
EVSYNC_EVEN_IRQ	VSYNC for even field: EVSYNC_EVEN interrupt has occurred at the end of the frame (EVSYNC received and the field polarity is even) (HDMI)
EVSYNC_ODD_IRQ	VSYNC for odd field: EVSYNC_ODD interrupt has occurred at the end of the frame (EVSYNC received and the field polarity is odd) (HDMI)
ACBIASCOUNTSTATUS1_IRQ	AC bias count status for LCD1 output: AC bias transition counter has decremented to 0.
ACBIASCOUNTSTATUS2_IRQ	AC bias count status for LCD2 output: AC bias transition counter has decremented to 0.
ACBIASCOUNTSTATUS3_IRQ	AC bias count status for LCD3 output: AC bias transition counter has decremented to 0.
PROGRAMMEDLINENUMBER_IRQ	Programmed line number: The primary LCD has reached the user programmed line number.
VID1ENDWINDOW_IRQ	End of the VID1 window: The DMA engine has fetched all the data from memory for the VID1 for the current frame.
VID2ENDWINDOW_IRQ	End of the VID2 window: The DMA engine has fetched all the data from memory for the VID2 for the current frame.
VID3ENDWINDOW_IRQ	End of the VID3 window: The DMA engine has fetched all the data from memory for the VID3 for the current frame.
GFXENDWINDOW_IRQ	End of the graphics window: The DMA engine has fetched all the data from memory for the graphics for the current frame.
VID1BUFFERUNDERFLOW_IRQ	VID1 DMA buffer underflow: The input VID1 DMA buffer goes underflow.
VID2BUFFERUNDERFLOW_IRQ	VID2 DMA buffer underflow: The input VID2 DMA buffer goes underflow.
VID3BUFFERUNDERFLOW_IRQ	VID3 DMA buffer underflow: The input VID3 DMA buffer goes underflow.
WBBUFFEROVERFLOW_IRQ	WB DMA buffer overflow: The output WB DMA buffer goes overflow. It cannot occur when WB channel is used in memory-to-memory transfer mode but only in capture mode. In capture mode the timings are defined by the timer associated with the output. In memory-to-memory mode, there is timing constraint.
GFXBUFFERUNDERFLOW_IRQ	GFX DMA buffer underflow: The input graphics DMA buffer goes underflow.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 10-24. DISPC Interrupts (continued)

Interrupt Name	Description
PALETTEGAMMALOADING_IRQ	Palette/gamma table loading: The palette/gamma table in the graphics pipeline has been loaded using the DISPC DMA engine.
WBUNCOMPLETEERROR_IRQ	The write-back buffer has been flushed before being fully drained. In WB capture mode, if the new frame starts before the WB DMA buffers are fully drained (onto external memory), then the contents of the WB DMA buffers are lost (implying last few pixels/lines are corrupted in the captured frame in memory). This interrupt is an indication of that, and will trigger every frame.
OCPERROR_IRQ	OCP error: L3_MAIN interconnect has sent SResp = ERR
SYNCLOST1_IRQ	Synchronization lost on LCD1 output: Occurs when VSYNC width/front or back porches are not wide enough to load the pipelines with data (LCD output).
SYNCLOST2_IRQ	Synchronization lost on LCD2 output: Occurs when VSYNC width/front or back porches are not wide enough to load the pipelines with data (LCD output).
SYNCLOST3_IRQ	Synchronization lost on LCD3 output: Occurs when VSYNC width/front or back porches are not wide enough to load the pipelines with data (LCD output).
SYNCLOSTTV_IRQ	Synchronization lost on TV output: Occurs when porches are not wide enough to load the pipelines with data (TV output connected to the HDMI).
WAKEUP_IRQ	Wakeup: Occurs when the SWakeUp signal is asserted.

10.2.4.5 DISPC DMA Requests

The DMA_SYSTEM synchronization line, DISPC_DREQ, is connected to the DMA_SYSTEM (DMA_SYSTEM_DREQ_5). This DMA request is not a classical one, but rather a synchronization signal between the DISPC and DMA_SYSTEM. The DMA_SYSTEM is informed that a programmable number of lines are output to the LCD and that a system memory can be updated. This request is related to the interrupt event PROGRAMMEDLINENUMBER_IRQ described in Table 10-24. This allows the DMA_SYSTEM channel to be synchronized with the internal DMA controller in the display subsystem.

In other words, it allows synchronizing a memory-to-memory frame buffer update based on the scan line of the frame buffer in system memory (SDRAM or SRAM) by the DISPC. The DISPC_DREQ request is generated at a programmable line number defined in the DISPC_LINE_NUMBER[11:0] LINENUMBER bit field. This process allows an application to use a single frame buffer and to update it after a certain number of lines are read by the DISPC.

10.2.4.6 DISPC DMA Engine

The DMA engine:

- Supplies data (encoded pixel data, palette, and gamma curve) from memories to the GFX, VID1, VID2, and VID3 pipelines through the interconnect based on the configuration of the DISPC and pipeline setting.
- Stores encoded pixel data from GFX/VID pipelines or overlays to memories through the WB pipeline and interconnect based on the configuration of the DISPC and WB pipeline setting.

Each pipeline has a dedicated buffer and a channel with independent settings. Table 10-25 lists the default size and allocation of the DMA buffer. Each DMA buffer is divided into two spaces, top and bottom. Depending on the application, a DMA buffer space can be associated to a pipeline or merged with other spaces. The total number of spaces for each pipeline is from 0 (pipeline inactive) to the number of pipelines × 2 (in that case, all the DMA buffers are associated to a single pipeline). The sum of the number of spaces allocated for each pipeline must not be greater than the maximum number of available spaces. The correct number of spaces must be allocated to ensure no underflow. The spaces allocated to each pipeline must be greater than or equal to the minimum number of spaces required to support the throughput and system latency. The space assignations are done in the DISPC_GLOBAL_BUFFER register.

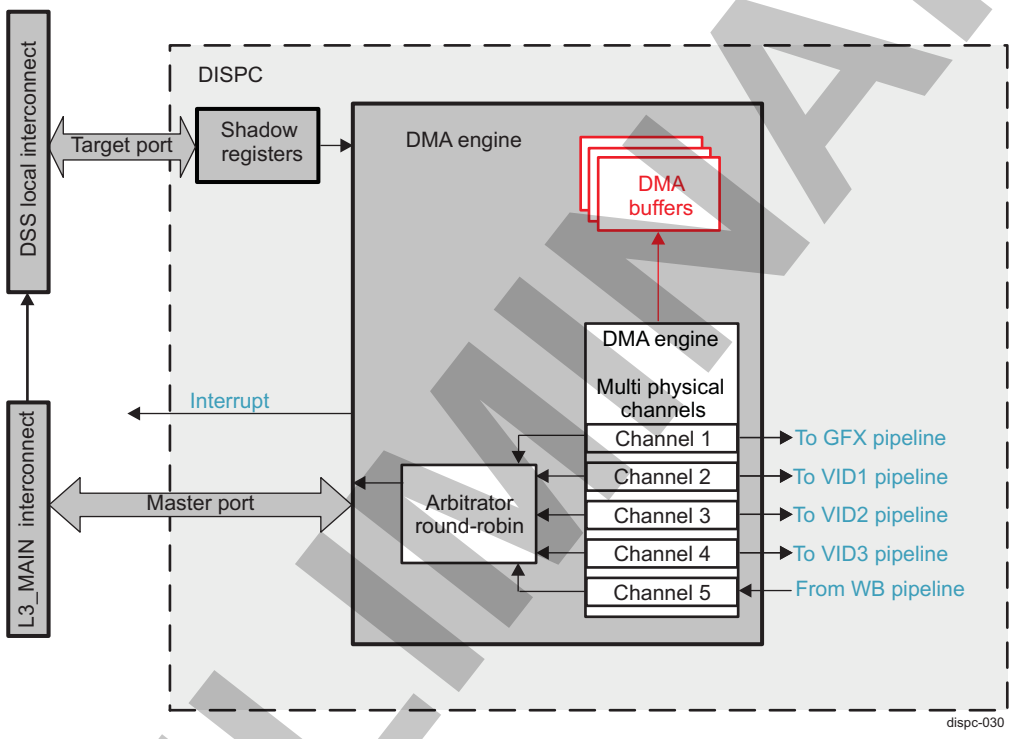
PRELIMINARY

Table 10-25. DISPC DMA Buffer Size

Pipelines	DMA Buffer Size
GFX	2 lines × 640 × 128 bits
VID1	2 lines × 1024 × 128 bits
VID2	2 lines × 1024 × 128 bits
VID3	2 lines × 1024 × 128 bits
WB	2 lines × 1024 × 128 bits

Figure 10-32 is an overview of the DMA engine.

Figure 10-32. DISPC DMA Engine Overview



10.2.4.6.1 DISPC

For each line to be fetched/stored, the DMA engine:

- Calculates the pixel address
- Aligns the address
- Defines the burst structure:
  - Type of burst (1D- or 2D-burst structure)
  - Length of the burst

The DMA engine generates scan addresses to read and write data to and from system memory. The base address defines the start address of the first pixel, and then the address is incremented based on the number of pixels per line, offset between two consecutive lines and number of lines. The byte address of each pixel in the frame buffer in the system memory is determined by:

Pixel address = Base address + x × bpp + (y × ((width × bpp) + increment))

where:

- Base address corresponds to the base address (for YUV–NV12 or YUV4:2:0-NV21 format) defined by:
  - DISPC_GFX_BA_0[31:0] BA bit field
  - DISPC_GFX_BA_1[31:0] BA bit field

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

  - DISPC_VIDp_BA_0[31:0] BA bit field
  - DISPC_VIDp_BA_1[31:0] BA bit field
  - DISPC_VIDp_BA_UV_0[31:0] BA bit field
  - DISPC_VIDp_BA_UV_1[31:0] BA bit field
- bpp corresponds to the number of bits per pixel defined by the DISPC_GFX_ATTRIBUTES[4:1] FORMAT bit field or the DISPC_VIDp_ATTRIBUTES[4:1] FORMAT bit field.
- width corresponds to the number of pixels per line defined by the DISPC_GFX_SIZE[11:0] SIZEX + 1 bit field or DISPC_VIDp_SIZE[11:0] SIZEX + 1 bit field.
- increment corresponds to the number of bytes to skip between two contiguous lines defined by the DISPC_GFX_ROW_INC[31:0] ROWINC – 1 bit field or the DISPC_VIDp_ROW_INC[31:0] ROWINC – 1 bit field.
- x corresponds to the pixel position on the x-axis.
- y corresponds to the pixel position on the y-axis.

NOTE: For YUV format, the pixel values are defined in two buffers (Y and UV). The base address of the Y buffers is defined in the DISPC_VIDp_BA_j[31:0] BA bit field. The base address of the UV buffers is defined in the DISPC_VIDp_BA_UV_j[31:0] BA bit field.

Table 10-26 summarizes the register settings for a simple access of a picture in the system memory.

Table 10-26. DISPC Register Settings for Accessing Image in Internal Memory

Registers	Value
DISPC_GFX_BA_j/DISPC_VIDp_BA_j/DISPC_WB_BA_j	PBA, the physical base address of image in the memory
DISPC_VIDp_BA_UV_j/DISPC_WB_BA_UV_j	PBA, the physical base address of UV buffers image in the memory
DISPC_GFX_PIXEL_INC/DISPC_VIDp_PIXEL_INC/DISPC_WB_PIXEL_INC	1 or other in pixel incremental value
DISPC_GFX_ROW_INC/DISPC_VIDp_ROW_INC/DISPC_WB_ROW_INC	1 or other in row incremental value

An interconnect request (128 bits) corresponds to one or several pixels, depending on the bits per pixel. Therefore, the DMA engine determines the appropriate burst sequence to optimize the fetching/storing of each new line. The DMA engine must prevent a single burst from crossing two lines. The DMA engine supports bursts of 2 × 128 bits, 4 × 128 bits, and 8 × 128 bits. The default burst size at reset time is 8 × 128 bits. The maximum burst size can be configured for each pipeline by setting the DISPC_GFX_ATTRIBUTES[7:6] BURSTSIZE or DISPC_VIDp_ATTRIBUTES[15:14] BURSTSIZE bit field. Because the burst size must be aligned to the burst boundary, in case of misalignment, the DMA engine may issue one request and/or smaller burst requests. Two types of burst are present which can be configured from the DISPC_GFX_ATTRIBUTES[29] BURSTTYPE or DISPC_VIDp_ATTRIBUTES[29] BURSTTYPE bit. Also, a force function is present configured from the DISPC_GFX_ATTRIBUTES[16] FORCE1DTILEDMODE or DISPC_VIDp_ATTRIBUTES[20] FORCE1DTILEDMODE or DISPC_WB_ATTRIBUTES[20] FORCE1DTILEDMODE bit for the following burst types:

- 1-D burst is used if the fetch/storage is linear in memory through the TILER. There is no rotation of the frame buffer. The frame buffer is not tiled.
- 2-D burst is used if the frame buffer is tiled.

Even if the DISPC_VIDp_ROW_INC register does not equal 1, the user can select 2-D burst. 2-D burst is used when the DISPC is configured to read one field of a frame by accessing only the even and odd lines.

NOTE: The burst size is initialized once at configuration and can be changed when the DISPC is disabled.

10.2.4.6.2 DISPC Immediate Base Address Flip Mechanism

The Flip Immediate mechanism is used to change of the fly the content of the frame buffer which is currently being displayed. The mechanism allows multiple changes (flips) of the base address (BA) during a frame. The mechanism is available for all pipelines (VID1, VID2, VID3, and GFX). Changes to the BA can be applied during the same line, or during different lines.

The following considerations must be considered:

- Data fetching from a new immediate BA is aligned with the data fetch mechanism of the DISPC DMA engine itself, and not with HSYNC or any other DISPC timing signal. After new VSYNC frame pulse, new BA is taken by hardware, as soon as the first set of lines is sent to internal pipeline of the DMA engine.
  - If multiple new BAs are written during the same line (before DMA engine acknowledges the first BA change), then programming steps 1 and 2 must be applied for each new BA (see the programming sequence in this section). The DMA takes only the last BA provided within the current line scan.
  - If multiple new BAs are written during different lines within the current frame, then programming steps 1 and 2 must be applied for each new BA (see the programming sequence in this section). The DMA takes the new BA each time it is updated.
- Immediate BA change cannot be achieved synchronously for two or more pipelines.
- Immediate BA change is possible only for BA0; it is not possible for BA1. Interlaced mode using BA0 and BA1 is not supported.
- Immediate BA change is supported only in RGB color space.

The Flip Immediate mechanism programming sequence follows:

1. Software writes the new immediate BA to the DISPC_GFX_BA_j register (where j=0) for the GFX pipeline, or to the DISPC_VID1_BA_j / DISPC_VID2_BA_j / DISPC_VID3_BA_j register (where j=0) for the required VID pipeline.
2. Software sets to 0x1 the corresponding EN bit for the required pipeline in the DISPC_BA0_FLIPIMMEDIATE_EN register.
3. The DISPC DMA engine, after completing its current line (or set of lines) fetch, takes the new immediate BA.
4. Hardware resets the EN bit in DISPC_BA0_FLIPIMMEDIATE_EN register and asserts a flip immediate IRQ. The IRQ can be enabled through the DISPC_IRQENABLE[31] FLIPIMMEDIATEDONE_EN bit. The status of the event is available in the DISPC_IRQSTATUS[31] FLIPIMMEDIATEDONE_IRQ bit.

10.2.4.6.3 DISPC DMA Buffers

10.2.4.6.3.1 DISPC READ DMA Buffers (GFX and VID Pipelines)

When the vertical front porch (VFP) period starts after the last horizontal front porch (HFP) of the last line or the external VSYNC is received, the DMA buffers are flushed according to the selected output associated with the pipeline. The DMA engine restarts fetching data from the memory through the L3_MAIN interconnect. Enabling or disabling the DISPC flushes the DMA buffers (except the WB DMA buffers).

Programmable high and low thresholds, independent for each DMA buffer, are used by the DMA engine to start and stop requesting data to the L3_MAIN interconnect.

- When low threshold (set in the DISPC_GFX_BUF_THRESHOLD[15:0] BUFLOWTHRESHOLD or DISPC_VIDp_BUF_THRESHOLD[15:0] BUFLOWTHRESHOLD bit field) is reached, the DMA engine starts a request on the L3_MAIN interconnect to fill the DMA buffer.
- When high threshold (set in the DISPC_GFX_BUF_THRESHOLD[31:16] BUFHIGHTHRESHOLD or DISPC_VIDp_BUF_THRESHOLD[31:16] BUFHIGHTHRESHOLD bit field) is reached, the DMA engine stops requesting encoded pixels.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

To avoid underflow at the beginning of a frame and have sufficient encoded pixel data to start some processing, a preloading of the DMA buffer is configurable between a fixed value of bytes or the high threshold value. The preload ensures a minimum number of pixels present in the buffer. When the preload value is reached, the associated channel must start pulling pixels out of the DMA buffer. To enable the preload based on the value entered in the DISPC_GFX_PRELOAD[11:0] PRELOAD or DISPC_VIDp_PRELOAD[11:0] PRELOAD bit field, the DISPC_GFX_BUF_THRESHOLD[11] BUFPRELOAD bit, or the DISPC_VIDp_BUF_THRESHOLD[19] BUFPRELOAD bit must be set to 0x0.

NOTE: When self-refresh mode is selected, meaning the data in the DMA buffers are used for multiple frames, and at the end of each frame, the DMA buffers are not flushed.

10.2.4.6.3.2 DISPC WRITE DMA Buffer (WB Pipeline)

Two modes are supported by the WB channel, selectable through the DISPC_WB_ATTRIBUTES[19] WRITEBACKMODE bit:

- Capture mode, WRITEBACKMODE bit set to 0: One of the overlay outputs going to LCD or TV outputs is captured and at the same time the data are sent on the output. The WB timings are controlled by the LCD or TV timings.
- Memory-to-memory mode, WRITEBACKMODE bit set to 1: One of the overlay outputs or one of the pipelines is captured to perform a memory-to-memory transfer, with some processing by the DISPC (rescaling, overlaying, color space conversion, etc.).

In capture mode: The WB DMA buffers are flushed when the VFP period starts after the HFP following the last line, or when the external VSYNC is received, depending on which output (LCD/TV) the WB pipeline is capturing data, if the programmed value in DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNT bit field is set to 0. If the programmed value in DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNT bit field is set to N (1:255), the write buffers DMA are flushed N lines later. The DMA engine starts storing data to memory through the L3_MAIN-based interconnect as soon as enough data is available for the programmed burst size. When enabling/disabling the DISPC, the DMA buffers are flushed. The programmable thresholds low and high are used by the DMA engine to start and stop sending data to the L3_MAIN interconnect.

NOTE: If the DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNT bit field is set to 0, the WB is reinitialized at the end of the last line of a frame at the beginning of the VFP signal. To let the WB complete the data write to the external memory, the highest possible value compatible with the vertical blanking period must be set.

NOTE: In WB capture mode, if a new frame starts before the WB DMA buffers contents are fully written onto external memory, then the contents of the WB DMA buffers are lost (implying last few pixels/lines are corrupted in the captured frame in memory). The DISPC_IRQSTATUS[26] WBUNCOMPLETEERROR_IRQ interrupt bit indicates this situation and triggers every frame. The WBUNCOMPLETEERROR interrupt can be enabled through the DISPC_IRQENABLE[26] WBUNCOMPLETEERROR_EN register bit.

Software can avoid this by delaying the flush of WB DMA buffers through proper programming of the DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNT bit field.

In memory-to-memory mode: The WB pipeline is not synchronized to any internal or external timing generator. The WB pipeline stores the output of one of the overlay outputs or one of the pipelines. When enabling or disabling the DISPC, the DMA buffers are flushed. The programmable thresholds low and high are used by the DMA engine to start and stop sending data to the L3_MAIN interconnect.

Programmable high and low thresholds are used by the DMA engine to start and stop sending data to the L3_MAIN interconnect.

- When high threshold (set in the DISPC_WB_BUF_THRESHOLD[31:16] BUFHIGHTHRESHOLD bit field) is reached, the DMA engine starts sending data on the L3_MAIN interconnect to empty buffer.
- When low threshold (set in the DISPC_WB_BUF_THRESHOLD[15:0] BUFLOWTHRESHOLD bit field)

Copyright © 2013, Texas Instruments Incorporated
PRELIMINARY

is reached, the DMA engine stops sending encoded pixels.

At the end of the frame, to completely drain the DMA buffer, some smaller bursts (even single requests) must be issued. To limit the number of interconnect requests from the DISPC, a number of IDLE cycles between requests can be inserted. IDLE cycles can be inserted only when WB is used in memory-to-memory mode. It is ignored when WB is in capture mode.

The number of IDLE cycles between requests can be activated and determined by:

- Setting the DISPC_WB_ATTRIBUTES[27] IDLESIZE bit to 0x0 (default value) and entering the number of idles between requests in the DISPC_WB_ATTRIBUTES[31:28] IDLENUMBER bit field. Idle numbers vary from 0 to 15.
- Setting the DISPC_WB_ATTRIBUTES[27] IDLESIZE bit to 0x1, which considers the size of the burst (the DISPC_WB_ATTRIBUTES[15:14] BURSTSIZE bit field) to determine the number of IDLE cycles.
  - If BURSTSIZE = 0x0, then the number of IDLE cycles equals IDLENUMBER (0 to 15).
  - If BURSTSIZE = 0x1, then the number of IDLE cycles equals IDLENUMBER × 4 (0 to 60).
  - If BURSTSIZE = 0x2, then the number of IDLE cycles equals IDLENUMBER × 8 (0 to 120).

10.2.4.6.4 DISPC MFLAG Mechanism and Arbitration

The MFLAG mechanism allows a dynamic increase of the priority of DISPC real-time traffic, when required, based on the fullness of the DISPC DMA read and write buffers.

The mechanism is implemented for all DMA buffers (GFX, VID1, VID2, VID3 and WB). Only high-priority pipelines can contribute to the MFLAG mechanism.

Programmable buffer thresholds (hysteresis) for each pipeline are used to indicate when the local MFLAG signal for each pipeline is generated. All local MFLAG signals are ORed to generate a single DSS MFLAG out band signal, which is provided to the L3 interconnect for granting OCP requests. The out band DSS MFLAG signal is asynchronous to any ongoing OCP transaction.

The threshold for each pipeline corresponds to the fullness of the associated DMA buffer, and is defined by two threshold parameters:

- HT_MFLAG: High threshold.
  - For read access from the GFX, VID1, VID2, and VID3 pipelines, when the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes low (deasserted).
  - For write access from the WB pipeline, when the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes high (asserted).
  - This threshold can be programmed in the following bit fields:
    - For the GFX pipeline in the DISPC_GFX_MFLAG_THRESHOLD[31:16] HT_MFLAG bit field
    - For the VID1 pipeline in the DISPC_VID1_MFLAG_THRESHOLD[31:16] HT_MFLAG bit field
    - For the VID2 pipeline in the DISPC_VID2_MFLAG_THRESHOLD[31:16] HT_MFLAG bit field
    - For the VID3 pipeline in the DISPC_VID3_MFLAG_THRESHOLD[31:16] HT_MFLAG bit field
    - For the WB pipeline in the DISPC_WB_MFLAG_THRESHOLD[31:16] HT_MFLAG bit field
- LT_MFLAG: Low threshold.
  - For read access from the GFX, VID1, VID2, and VID3 pipelines, when the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes high (asserted).
  - For write access from the WB pipeline, when the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes low (deasserted).
  - This threshold can be programmed in the following bit fields:
    - For the GFX pipeline in the DISPC_GFX_MFLAG_THRESHOLD[15:0] LT_MFLAG bit field
    - For the VID1 pipeline in the DISPC_VID1_MFLAG_THRESHOLD[15:0] LT_MFLAG bit field
    - For the VID2 pipeline in the DISPC_VID2_MFLAG_THRESHOLD[15:0] LT_MFLAG bit field
    - For the VID3 pipeline in the DISPC_WB_MFLAG_THRESHOLD[15:0] LT_MFLAG bit field
    - For the WB pipeline in the DISPC_WB_MFLAG_THRESHOLD [15:0] LT_MFLAG bit field

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

By default, the MFLAG mechanism is disabled (DISPC_GLOBAL_MFLAG_ATTRIBUTE[1:0] MFLAG_CTRL bit field = 0x0), and the DSS MFLAG out band signal is low (deasserted). The arbitration scheme for the DISPC pipelines is the same as described in Section 10.2.4.6.7, *DISPC Arbitration*. That is, round-robin either between high-priority pipelines, or between normal-priority pipelines (if all pipelines are of normal priority).

When the DISPC_GLOBAL_MFLAG_ATTRIBUTE[1:0] MFLAG_CTRL bit field is set to 0x2, the MFLAG mechanism is enabled, and the DSS MFLAG out band signal is dynamically set to 0 or 1, depending on DMA buffers fullness and programmed threshold levels, as explained previously in this section. In this case, the arbitration scheme for DISPC pipelines is round-robin between those high-priority pipelines, which have asserted local MFLAG signals. If there are no high-priority pipelines with asserted local MFLAG signals, then the arbitration scheme is the same as described in Section 10.2.4.6.7, *DISPC Arbitration*.

The DISPC_GLOBAL_MFLAG_ATTRIBUTE[2] MFLAG_START bit defines additional rules for the MFLAG mechanism:

- If the MFLAG_START bit is set to 0x0 (default value), then in the beginning of the frame when the DMA buffer is empty, the local MFLAG signal of each pipeline is kept at 0 until PRELOAD is reached (for more information on preloading, see Section 10.2.4.6.3.1, *DISPC READ DMA Buffers (GFX and VID Pipelines)*. Then, based on the setting of the DISPC_GLOBAL_MFLAG_ATTRIBUTE[1:0] MFLAG_CTRL bit field, the MFLAG signal is generated and internal logic is arbitrating between pipeline requests.
- If the MFLAG_START bit is set to 0x1, then even in the beginning of the frame when the DMA buffer is empty, the DISPC_GLOBAL_MFLAG_ATTRIBUTE[1:0] MFLAG_CTRL bit field defines the generation of the MFLAG signal for each pipeline.

10.2.4.6.5 DISPC Predecimation

The predecimation process consists of downscaling an image by fetching only the necessary pixels in the memory. Vertical and horizontal predecimation are possible:

- Vertical predecimation: The picture stored in memory can be predecimated vertically by skipping lines. Burst mode is used to fetch the data when skipping lines. Only the lines that will be used by the DISPC are fetched from memory; the other lines are skipped. The DMA engine sends requests only for the useful lines using 1-D or 2-D burst, depending on the setting. The base address indicates the first valid pixel to fetch from memory. The number of lines to skip is set in the DISPC_GFX_ROW_INC[31:0] ROWINC or DISPC_VIDp_ROW_INC[31:0] ROWINC bit field.

  NOTE: When 2-D burst mode is used, the access to data in memory is performed through the TILER module of DMM (for more details, see , *TILER Overview*, in Chapter 15, *Memory Subsystem*), and as a result a maximum of one line can be skipped.

- Horizontal predecimation: When fetching data from memory, it is possible to skip 1 of 2 pixel data containers, up to 1 of 16 pixel data containers, by setting the DISPC_GFX_PIXEL_INC[7:0] PIXELINC or DISPC_VIDp_PIXEL_INC[7:0] PIXELINC bit field to the number of pixel data containers to skip (n), multiplied by the size of a pixel data container (in bytes), + 1. See the following note for more details.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: The restriction to horizontal predecimation is that there is at least one useful pixel per 128-bit request. In that case, the DMA engine uses burst mode instead of singles to optimize the requests in terms of latency and SDRAM efficiency.

No decimation is supported when the input format is 1, 2, 4, or 8 BITMAP.

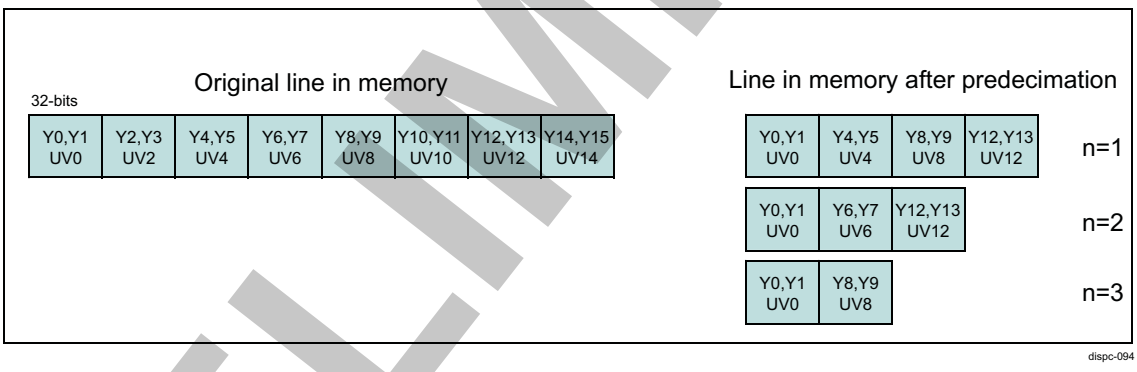
For RGB and YUV4:2:0 data formats, each pixel data container in memory holds 1 pixel. Thus, when configuring the PIXELINC bit field, the value of n equals the number of pixels to skip:

- For RGB format, one pixel data container = 32 bits = 1 pixel
- For YUV format:
  - One Y pixel data container = 8 bits = 1 pixel
  - One UV pixel data container = 16 bits = 1 pixel

For YUV4:2:2 format, each 32-bit pixel data container holds the Luma components for 2 pixels, and the Chrominance component of 1 pixel (see Figure 10-33). Therefore, for the valid values of the PIXELINC bit field in the case of the following YUV4:2:2 format, caution must be taken because n equals the number of pixel data containers to skip, not the number of pixels:

- For n = 1, PIXELINC = 5
- For n = 2, PIXELINC = 9
- For n = 3, PIXELINC = 13
- For n = 4, PIXELINC = 17, etc.

Figure 10-33. YUV4:2:2 Predecimation



10.2.4.6.6 DISPC Progressive-to-Interlaced Format Conversion

The DMA engine can be used to perform YUV4:2:0 NV12 and YUV4:2:0 NV21 progressive-to-interlaced data conversion with 0-degree orientation. This section provides generic approach details.

Two possible configurations are available, depending on the setting of the DISPC_VIDp_ATTRIBUTES[22] DOUBLESTRIDE bit, which defines the stride of each pixel value buffer for the YUV format. The following must be considered for both configurations:

- The DISPC_VIDn_BA_j[31:29] BA and DISPC_VIDn_BA_UV_j[31:29] BA bit fields, and the DISPC_VIDn_ATTRIBUTES[13:12] ROTATION bit field must be set to 0x0 to indicate 0-degree orientation.
- The DISPC_VIDn_BA_j[31:29] BA and DISPC_VIDn_BA_UV_j[31:29] BA bit fields must be set to 0x3, and the DISPC_VIDn_ATTRIBUTES[13:12] ROTATION bit field must be set to 0x2 to indicate 180-degree orientation.

Configuration 1 – YUV4:2:0 progressive to interlaced conversion

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The DISPC_VIDp_ATTRIBUTES[22] DOUBLESTRIDE bit is set to 0x1. The CbCr container is twice the size of the Y container. All Luma and Chroma lines for even and odd fields are fetched from memory. The scaler unit of the respective pipeline can be used to downscale by 2 (through filtering) the fetched data to create the interlaced output. For more information about the scaler configuration, see Section 10.2.4.10.4, *Scaler Unit*.

Configuration 2 – YUV4:2:0 progressive to YUV4:2:2 interlaced conversion

The DISPC_VIDp_ATTRIBUTES[22] DOUBLESTRIDE bit is set to 0x0. The CbCr container is the same size as the Y container. The DISPC_VIDn_ROW_INC register for the respective pipeline must be configured so that only the Y data is vertically predecimated by 2 (for more information, see Section 10.2.4.6.5, *Predecimation*). The CbCr data must not be predecimated. As a result, only the even Luma lines for the even field and the odd Luma lines for the odd field are fetched from memory. To create the interlaced output, all the Chroma lines are fetched from memory.

10.2.4.6.7 DISPC Arbitration

The requests (reads or writes) sent to the L3_MAIN interconnect are pipelined and arbitrated in a round-robin scheme. The default arbitration scheme must be modified by setting the priority attribute of each pipeline as defined in the following bits:

- DISPC_GFX_ATTRIBUTES[14] ARBITRATION
- DISPC_VIDp_ATTRIBUTES[14] ARBITRATION
- DISPC_WB_ATTRIBUTES[14] ARBITRATION

By default, all pipelines have the same priority (normal), which means all pipeline requests are treated in a round-robin order manner. If one or more pipelines require a higher number of requests going to the L3_MAIN interconnect, its priority can be moved up to high priority. In this case, the high-priority pipeline is granted access before any pipeline in normal priority. If more than one active pipeline is in high priority, the behavior is the same as all active pipelines in normal priority. Normal active pipelines are not treated until all high active pipelines are finished. The ARBITRATION bit cannot be modified during the entire frame.

This functionality balances the bandwidth of the pipeline depending on its constraint. It can be used to give higher priority to the pipelines with real-time constraints versus non-real-time pipelines. For example, pipelines associated with the LCD output in stall mode must have lower priority than pipelines associated with TV output.

10.2.4.6.8 DISPC DMA Power Modes

10.2.4.6.8.1 DISPC DMA Low-Power Mode

Each DMA buffer is divided into two spaces. Each space can be associated with the pipeline or merged with other DMA buffers. The total number of DMA buffers for each pipeline is from 0 (pipeline inactive) to the number of pipelines × 2 (in that case all the DMA buffers are associated with a single pipeline). The sum of the number of DMA buffers allocated for each pipeline must not be greater than the maximum available. The correct number of DMA buffers must be allocated to ensure no underflow. The number of DMA buffers allocated to each pipeline must be greater than or equal to the minimum required to support the throughput and the system latency.

NOTE: When the number of buffers is changed, the thresholds must be reprogrammed to reflect the new configuration of the DMA buffer.

10.2.4.6.8.2 DISPC DMA Ultralow-Power Mode

In low-power mode, the L3_MAIN interconnect is used to fill up the DMA buffers to store all the data required to display a full frame. The L3_MAIN interconnect is not used to fetch new pixels for the following frames. The data in the DMA buffer are reused to display on the screen.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The setting of the mode is independent for each pipeline. One pipeline may have all the frame pixels in its DMA buffer and the other pipelines may have to refill their respective DMA buffers along the display scan because the frame buffer is too big to be stored in the DMA buffer.

The DMA buffers can be merged to optimize the L3_MAIN interconnect off time. Merging the DMA buffers into a single buffer can be used at the same time to improve ultralow-power mode (see Section 10.2.4.6.8.1, *Low-Power Mode*).

During the time in which the frames are fetched in the internal DMA buffer, MStandby must be asserted if the DISPC_SYSCONFIG[13:12] MIDLEMODE bit field is set to 0x2 (smart-standby mode).

Two ultralow-power modes can be entered manually or automatically:

- Self-refresh mode: Starting self-refresh mode is done manually by setting the DISPC_GFX_ATTRIBUTES[15] SELFREFRESH or DISPC_VIDp_ATTRIBUTES[15] SELFREFRESH bit to 0x1 after capturing a frame in the DMA buffers. Self-refresh mode is stopped by setting the SELFREFRESH bit to 0x0.
- Automatic self-refresh mode: By setting the DISPC_GFX_ATTRIBUTES[17] SELFREFRESHAUTO or DISPC_VIDp_ATTRIBUTES[17] SELFREFRESHAUTO bit to 0x1, the transition from off to on self-refresh mode is done by hardware after capturing the first frame. The hardware reflects the status of the self-refresh mode by setting the SELFREFRESH bit to 0x1, which means that the data are read inside the DMA buffer without accessing the interconnect and system memory during the frame. Setting the SELFREFRESH bit to 0x0 updates the DMA buffer.

NOTE: The WB pipeline does not support ultralow-power mode.

10.2.4.7 DISPC Rotation and Mirroring

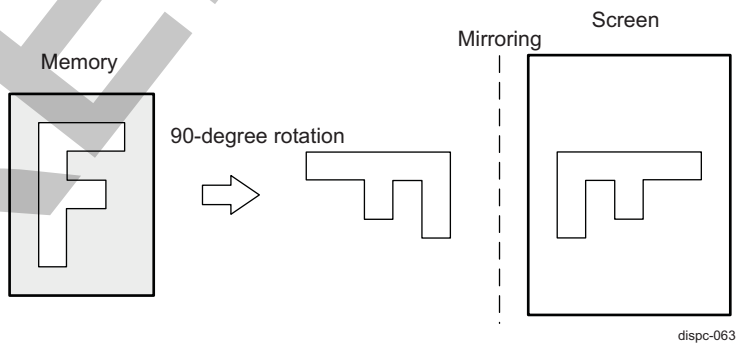
The DISPC provides flexible mechanisms for efficient implementation of rotation using the DISPC, its DMA engine, and the rotation engine of the TILER. The rotation is handled only through the TILER, which supplies the encoded pixels to the DISPC.

NOTE: No rotation or mirroring is supported when accessing internal SDRAM directly.

The TILER supports:

- Rotation: 0-, 90-, 180-, and 270-degree views
- Mirroring
- Any combination of rotation and mirroring (for example, Rot-90 + mirroring)

Figure 10-34. DISPC 90-Degree Rotation With Mirroring



When accessing YUV4:2:2 data, each 32-bit value loaded into the DMA buffer can represent either:

- Two consecutive pixels on the same line (for instance, 0- to 180-degree rotation)
- Two pixels adjacent vertically (for instance, 90- to 270-degree rotation)

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The reading from the DMA buffer supports the extraction of the two pixels, regardless of the rotation. When the pixels are not consecutive on the same line (90- to 270-degree rotation), the chrominance sample of the first pixel of each 32-bit value is duplicated for the second pixel in the same 32-bit value.

The rotation flag DISPC_VIDn_ATTRIBUTES[13:12] ROTATION and DISPC_VIDn_ATTRIBUTES[4:1] FORMAT bit fields define the processing to extract the pixels from YUV4:2:2 32-bit values. Software must ensure that the settings of the ROTATION and FORMAT bit fields are coherent with the rotation and mirroring defined through the address format in the TILER-specific address map. For more information, see , *Dynamic Memory Manager*, in *Chapter 15, Memory Subsystem*.

NOTE: For YUV4:2:0 NV12, 2D tiled memory access cases, the DISPC_VIDn_ATTRIBUTES[13:12] ROTATION bit field should be set properly to match with the intended rotation of the use case.

Table 10-27 describes the register settings of the DISPC when accessing, rotating, and mirroring an image using the TILER. A physical base address (PBA) for each rotation is determined and set as the buffer address (BA). The row incremental is determined and set in ROW_INC. The value of the pixel increment, PIXEL_INC, is set to 0x1 (contiguous pixels).

Table 10-27. DISPC Register Settings for Rotation Using TILER

Rotation	Registers	Rotation With and Without Mirroring
0 degree	DISPC_GFX_BA_j/DISPC_VIDp_BA_j/DISPC_WB_BA_j	PBA0
	DISPC_GFX_PIXEL_INC/DISPC_VIDp_PIXEL_INC/DISPC_WB_PIXEL_INC	1 to 16
	DISPC_GFX_ROW_INC/DISPC_VIDp_ROW_INC/DISPC_WB_ROW_INC	ROW0
90 degrees	DISPC_GFX_BA_j/DISPC_VIDp_BA_j/DISPC_WB_BA_j	PBA90
	DISPC_GFX_PIXEL_INC/ DISPC_VIDp_PIXEL_INC/DISPC_WB_PIXEL_INC	1 to 16
	DISPC_GFX_ROW_INC/ DISPC_VIDp_ROW_INC/DISPC_WB_ROW_INC	ROW90
180 degrees	DISPC_GFX_BA_j/DISPC_VIDp_BA_j/DISPC_WB_BA_j	PBA180
	DISPC_GFX_PIXEL_INC/DISPC_VIDp_PIXEL_INC/DISPC_WB_PIXEL_INC	1 to 16
	DISPC_GFX_ROW_INC/ DISPC_VIDp_ROW_INC/DISPC_WB_ROW_INC	ROW180
270 degrees	DISPC_GFX_BA_j/DISPC_VIDp_BA_j/DISPC_WB_BA_j	PBA270
	DISPC_GFX_PIXEL_INC/DISPC_VIDp_PIXEL_INC/DISPC_WB_PIXEL_INC	1 to 16
	DISPC_GFX_ROW_INC/ DISPC_VIDp_ROW_INC/DISPC_WB_ROW_INC	ROW270

NOTE: For YUV format, in addition to the DISPC_VIDp_BA_j register used for the Y component, the DISPC_VIDp_BA_UV_j register must be set to define the base address of the UV frame buffer in memory.

The PBA rotation is determined by:

- PBA0 = PBA | (mode << 27) | (orientation << 29) | (1<<32)
- PBA90 = PBA | (mode << 27) | (orientation << 29) | (1<<32)
- PBA180 = PBA | (mode << 27) | (orientation << 29) | (1<<32)
- PBA270 = PBA | (mode << 27) | (orientation << 29) | (1<<32)

Where PBA is the physical base address of the image in the memory.

The ROW rotation is determined by:

- If 8 bits per pixel:
  - ROW0 = 16384: Width of the video picture in memory (in bytes) + 1
  - ROW90 = 8192: Width of the video picture in memory (in bytes) + 1
  - ROW180 = 16384: Width of the video picture in memory (in bytes) + 1
  - ROW270 = 8192: Width of the video picture in memory (in bytes) + 1

Copyright © 2013, Texas Instruments Incorporated
PRELIMINARY

- If 16 bits per pixel:
  - ROW0 = 32768: Width of the video picture in memory (in bytes) + 1
  - ROW90 = 8192: Width of the video picture in memory (in bytes) + 1
  - ROW180 = 32768: Width of the video picture in memory (in bytes) + 1
  - ROW270 = 8192: Width of the video picture in memory (in bytes) + 1
- If 32 bits per pixel:
  - ROW0 = 32768: Width of the video picture in memory (in bytes) + 1
  - ROW90 = 16384: Width of the video picture in memory (in bytes) + 1
  - ROW180 = 32768: Width of the video picture in memory (in bytes) + 1
  - ROW270 = 16384: Width of the video picture in memory (in bytes) + 1

Table 10-28 and Table 10-29 list the DISPC rotation mode and rotation orientation definitions, respectively.

Table 10-28. DISPC Rotation Mode Definition

	8-Bit Tiled	16-Bit Tiled	32-Bit Tiled	Page Tiled
Mode	0	1	2	3

Table 10-29. DISPC Rotation Orientation Definition

Type of Orientation	Value
0-degree view	0x0
180-degree view with mirroring	0x1
0-degree view with mirroring	0x2
180-degree view	0x3
270-degree view with mirroring	0x4
270-degree view	0x5
90-degree view	0x6
90-degree view with mirroring	0x7

NOTE: For YUV4:2:0 progressive pixel format, because the value of the DISPC_VIDp_ROW_INC register is defined for the Y buffer, the DISPC_VIDp_ATTRIBUTES[22] DOUBLESTRIDE bit must be set to 1 when rotating the picture by 0 and 180 degrees, and must be reset to 0 when rotating the picture by 90 and 270 degrees.

For YUV4:2:0 interlaced pixel format, because the value of the DISPC_VIDp_ROW_INC register is defined for the Y buffer, the DISPC_VIDp_ATTRIBUTES[22] DOUBLESTRIDE bit must be set to 1 when rotating the picture by 0 and 180 degrees. Rotations of 90 and 270 degrees are not supported with this pixel format.

10.2.4.8 DISPC Memory Format

The graphic and video pipelines support various types of memory formats. Table 10-30 lists all supported formats for each pipeline. Nibble mode is enabled by setting the DISPC_GFX_ATTRIBUTES[9] NIBBLEMODE bit to 0x1 and applies only to BITMAP format for the GFX pipeline.

Table 10-30. DISPC Memory Formats Supported

10.2.4.9 DISPC Graphics Pipeline

The graphics pipeline is connected to the GFX FIFO for the input port and to the four overlay managers for the output or WB pipeline. The pixel output is directed to an LCD, TV, or WB path by setting the DISPC_GFX_ATTRIBUTES[8] CHANNELOUT bit and the DISPC_GFX_ATTRIBUTES[31:30] CHANNELOUT2 bit field. Table 10-48 lists the bit field settings to orient a pipeline to an LCD, TV, or WB output. The default value directs the GFX pipeline to LCD1. The GFX pipeline can be enabled by setting the DISPC_GFX_ATTRIBUTES[0] ENABLE bit to 0x1.

NOTE: It is not possible to change the direction of the GFX pipeline on the fly. If the graphics pipeline must be connected to an overlay manager different from the one to which it is currently connected, then the following steps must be performed:

1. Disable the GFX pipeline by setting the DISPC_GFX_ATTRIBUTES[0] ENABLE bit to 0x0.
2. Direct the GFX pipeline to the new overlay manager by modifying the DISPC_GFX_ATTRIBUTES[8] CHANNELOUT and [31:30] CHANNELOUT2 bits.
3. Disable the DISPC output which corresponds with the overlay manager to which the GFX pipeline will be connected next. This is done by setting the in the following bits to 0x0 for the listed outputs:
   - The DISPC_CONTROL1[0] LCDENABLE bit for LCD1 output
   - The DISPC_CONTROL2[0] LCDENABLE bit for LCD2 output
   - The DISPC_CONTROL3[0] LCDENABLE bit for LCD3 output
   - The DISPC_CONTROL1[1] TVENABLE bit for TV output
4. Enable the GFX pipeline by setting the DISPC_GFX_ATTRIBUTES[0] ENABLE bit to 0x1.
5. Enable the DISPC output that corresponds with the overlay manager to which the GFX pipeline will be connected. This is done by setting the following bits to 0x1 for the listed outputs:
   - The DISPC_CONTROL1[0] LCDENABLE bit for LCD1 output
   - The DISPC_CONTROL2[0] LCDENABLE bit for LCD2 output
   - The DISPC_CONTROL3[0] LCDENABLE bit for LCD3 output
   - The DISPC_CONTROL1[1] TVENABLE bit for TV output

The pipeline consists of programmable replication logic, an antiflicker filter, and one 256-entry palette table. The replication logic is used to convert the RGB pixel formats into an ARGB40-based format. The antiflicker filter processes the graphics data in RGB format to remove some of the vertical flicker. The 256-entry palette is used to convert bitmap formats into RGB formats or for gamma corrections when RGB format is inputted.

Table 10-30 lists the input formats supported by the graphics pipeline.

Figure 10-35 shows the graphics pipeline.

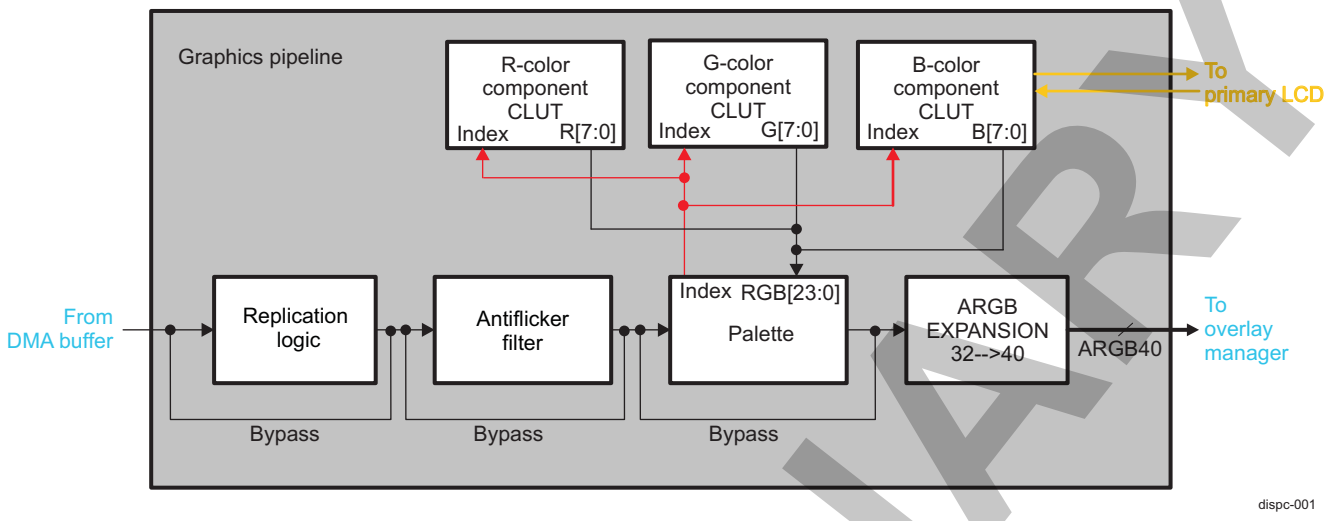
Figure 10-35. DISPC Graphics Pipeline



10.2.4.9.1 DISPC Replication Logic

The replication logic increases the color depth of the graphics-encoded pixels (from true color RGB 12, and 16 to 40 bpp).

- When the replication logic is enabled by setting the DISPC_GFX_ATTRIBUTES[5] REPLICATIONENABLE bit to 0x1, the MSBs are copied to the missing LSB. Table 10-31 describes the remapping of the RGB pixels into ARGB 40-bit values.

Table 10-31. DISPC Replication Enabled: RGB Pixel Formats Remapping Into ARGB40-10.10.10.10

10.2.4.9.2 DISPC Antiflicker Filter

The antiflicker filter processes the graphics data to remove some of the vertical flicker. It is based on a 3-tap FIR filter with fixed coefficients. For each pixel to be output from the graphics pipeline, the pixel above and below the current line must be read from the DMA graphics FIFO. Therefore, three lines of pixels must be stored in the DMA graphics FIFO.

The antiflickering equations for A, R, G, and B components are:

$A_{out}(x,y) = 0.25 \times A_{in}(x,y-1) + 0.5 \times A_{in}(x,y) + 0.25 \times A_{in}(x,y+1)$

$R_{out}(x,y) = 0.25 \times R_{in}(x,y-1) + 0.5 \times R_{in}(x,y) + 0.25 \times R_{in}(x,y+1)$

$G_{out}(x,y) = 0.25 \times G_{in}(x,y-1) + 0.5 \times G_{in}(x,y) + 0.25 \times G_{in}(x,y+1)$

$B_{out}(x,y) = 0.25 \times B_{in}(x,y-1) + 0.5 \times B_{in}(x,y) + 0.25 \times B_{in}(x,y+1)$

For the first line of processing, because there is no pixel above, the value (x,y) is duplicated.

$Out(x,y) = 0.25 \times In(x,y) + 0.5 \times In(x,y) + 0.25 \times In(x,y+1)$

For the last line of processing, because there is no pixel below, the value (x,y) is duplicated.

$Out(x,y) = 0.25 \times In(x,y-1) + 0.5 \times In(x,y) + 0.25 \times In(x,y)$

NOTE: Antiflicker filtering is supported only in RGB formats and not in BITMAP formats.

Antiflickering is not supported for pictures with fewer than two lines. In this case, the user must disable the antiflickering processing.

By default, the antiflicker filtering is disabled. It can be enabled by setting the DISPC_GFX_ATTRIBUTES[24] ANTIFLICKER bit to 0x1.

10.2.4.9.3 DISPC Color Look-Up Table (CLUT)

The graphics pipeline supports conversion of the BITMAP formats into RGB24 formats through a palette table. To enable palette mode, the DISPC_CONFIG1[3] PALETTEGAMMATABLE bit must be set to 0x0. Figure 10-36 shows the internal architecture of the color look-up/gamma table.

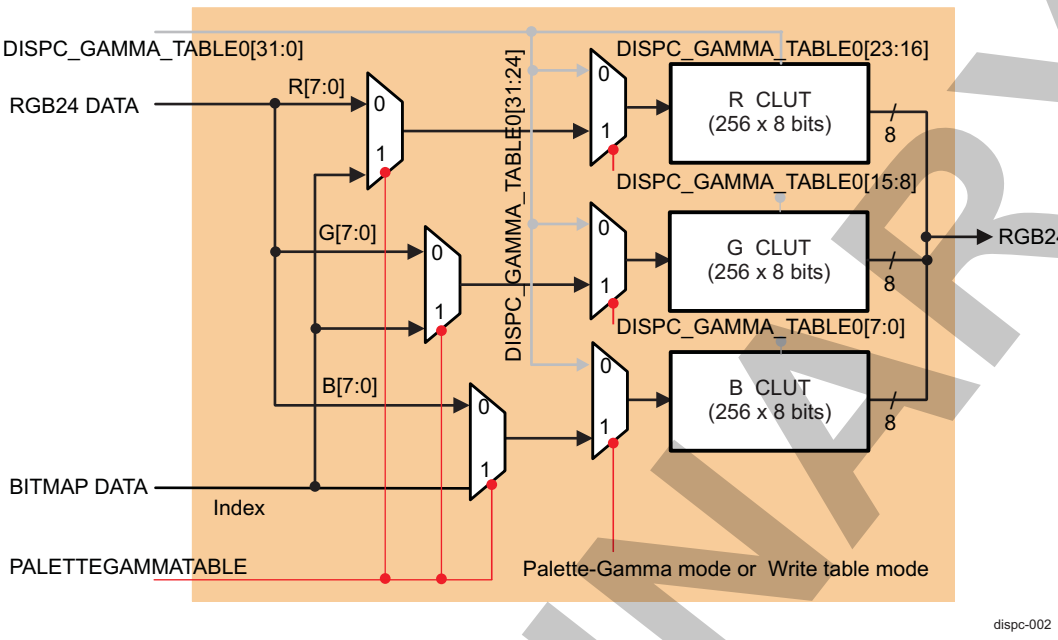
The palette is split into three memories of 256-bit × 8-bit entries. For bitmap (CLUT) indexes, the same value (1, 2, 4, or 8 bpp) indexes the three memories. The table can be reloaded every frame, once, or never (at the beginning of the frame before fetching pixels for the graphics). The table is loaded dynamically at the beginning of the frame by the DISPC DMA engine. The base address of the table buffer is set in the DISPC_GFX_TABLE_BA[31:0] TABLEBA bit field. It is possible to load the table for every frame or only for a specific frame by setting the DISPC_CONFIG1[2:1] LOADMODE bit field.

The table can be loaded without fetching data for the graphics pipeline. The DMA buffer associated with the graphics pipeline is used to fetch the table from memory. Regardless of the mode (color or monochrome) for each entry into the table, one 32-bit value is fetched from memory.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-36. DISPC Palette/Gamma Correction Architecture



The palette mode uses the encoded pixel values from the input graphics FIFO as pointers to index the 24-bit-wide palette: 1-bpp pixel address 2 palette entries, 2-bpp pixel address 4 palette entries, 4-bpp pixel address 16 palette entries, and 8-bpp pixel address 256 palette entries. In color mode, the value within the palette consists of three 8-bit fields, one for each color component: red, green, and blue (see Figure 10-37). For a color operation, an individual frame is limited to a selection of 256 colors (the number of palette entries). In monochrome mode, only one 8-bit value is present; 256 grayscales and 16,777,216 colors are obtained after passing through the palette (see Figure 10-38)

Figure 10-37. DISPC Data Memory Organization: Color Mode

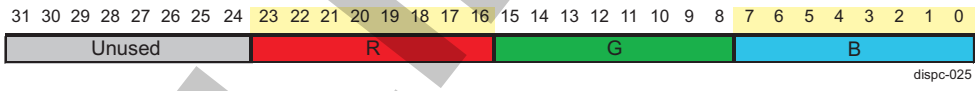


Figure 10-38. DISPC Data Memory Organization: Gray Mode

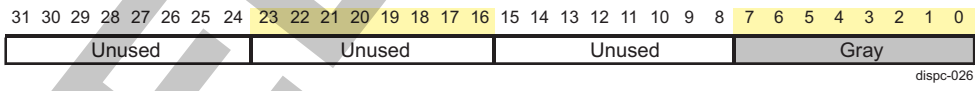

When a palette entry is selected by the encoded pixel value, the content of the entry and the index are sent to the LCD1 overlay manager.

In gamma curve mode, the selected encoded pixel values based on the color keys by the overlay manager from the video or grahics paths are sent to the gamma curve table. Each component of encoded pixel value is used as a pointer to index 1 out of 256 24-bit gamma curve entries in the table. Each 8-bit component is replaced with the 8-bit table value corresponding to the R, G, or B component. Figure 10-39 describes the format of one of the gamma curve values in the memory.

Figure 10-39. DISPC Data Memory Organization: Gamma Curve 24 BPP

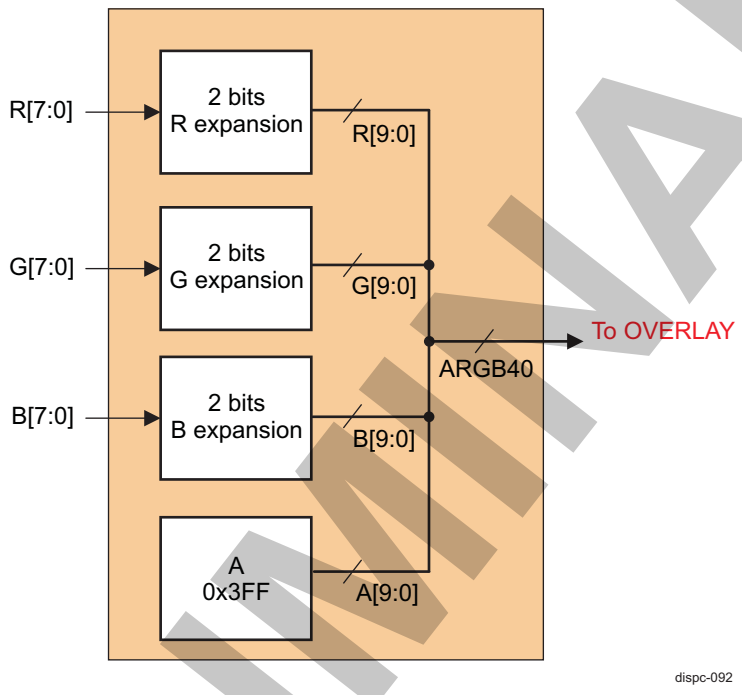
10.2.4.9.4 DISPC Expansion to ARGB40

When the GFX pipeline input data is in an RGB pixel format, the expansion to ARGB40 format is done as described in Section 10.2.4.10.1, *DISPC Replication Logic*.

When the GFX pipeline input data is in BITMAP format, the expansion module input receives the RGB24 pixel format output from the pallette module. The expansion module automatically replicates the 2 MSBs of each color component to create an ARGB40 pixel with the A component set to 0x3FF (see Figure 10-40).

Figure 10-40. DISPC Expansion to ARGB40



10.2.4.10 DISPC Video Pipelines

Three identical video pipelines are available, VID1, VID2, and VID3. Each video pipeline is connected to its video FIFO controller for the input port and to the four overlay managers, LCD1, LCD2, LCD3, and TV or WB pipeline. The pixel output is directed to the LCD, TV, or WB path by setting the DISPC_VIDp_ATTRIBUTES[16] CHANNELOUT bit and the DISPC_VIDp_ATTRIBUTES[31:30] CHANNELOUT2 bit field. Table 10-48 summarizes the bit field settings to orient a pipeline to LCD, TV, or WB output. The default value directs all video pipelines to LCD1.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: It is not possible to change the direction of the video pipelines on the fly. If a video pipeline needs to be connected to a different overlay manager than what it is currently connected, then the following steps need to be performed:

1. Disable the VIDp pipeline by setting the DISPC_VIDp_ATTRIBUTES[0] ENABLE bit to 0x0.
2. Direct the VIDp pipeline to the new overlay manager by modifying the [16] CHANNELOUT bit and the [31:30] CHANNELOUT2 bit in the DISPC_VIDp_ATTRIBUTES register.
3. Disable the DISPC output that corresponds with the overlay manager to which the VIDp pipeline will be connected next. This is done by setting the following bits to 0x0 for the listed outputs:
   - The DISPC_CONTROL1[0] LCDENABLE bit for LCD1 output
   - The DISPC_CONTROL2[0] LCDENABLE bit for LCD2 output
   - The DISPC_CONTROL3[0] LCDENABLE bit for LCD3 output
   - The DISPC_CONTROL1[1] TVENABLE bit for TV output
4. Enable the VIDp pipeline by writing 0x1 to the DISPC_VIDp_ATTRIBUTES [0] ENABLE bit.
5. Enable the DISPC output that corresponds with the overlay manager to which the VIDp pipeline will be connected next. This is done by setting the following bits to 0x1 for the listed outputs:
   - The DISPC_CONTROL1[0] LCDENABLE bit for LCD1
   - The DISPC_CONTROL2[0] LCDENABLE bit for LCD2 output
   - The DISPC_CONTROL3[0] LCDENABLE bit for LCD3 output
   - The DISPC_CONTROL1[1] TVENABLE bit for TV output

A video pipeline consists of a scaler unit, color space conversion (CSC) unit, VC-1 range mapping unit, and some programmable replication logic. The order of the video pipeline unit can be configured in two manners (see Figure 10-41 and Figure 10-42):

- Configuration 1 (YUVCHROMARESAMPLING = 0): VC-1 range mapping unit followed by a CSC unit and then a scaler unit. The configuration is used to support RGB, ARGB, and RGBA formats and YUV4:2:2 in backward mode for both data types. Each block can be independently bypassed.
- Configuration 2 (YUVCHROMARESAMPLING = 1): VC-1 range mapping unit followed by a scaler unit and then a CSC unit. The configuration is used to support RGB, ARGB, and RGBA formats and YUV4:2:2, YUV420-NV12, and YUV420-NV21 formats, taking advantage of the scaler to resample the chrominance using five taps horizontally and three or five taps vertically. Each block can be independently bypassed.

The DISPC_VIDn_ATTRIBUTES2[8] YUVCHROMARESAMPLING bit controls the order of the scaler unit in the video pipeline:

- When the YUVCHROMARESAMPLING bit is set to 0x0, the video pipeline is in configuration 1, and the scaler comes after the CSC unit. In case of YUV input data in 4:2:2 format, the chrominance resampling (4:2:2 to 4:4:4 format) is done by averaging the chrominance adjacent samples for only 0 degrees (zero rotation), because other rotation (90/180/270 degrees) is not supported in this mode. For more information about the supported chrominance resampling methods, see Section 10.2.4.10.3.1, *Chrominance Resampling*.
- When the YUVCHROMARESAMPLING bit is set to 0x1, the video pipeline is in configuration 2, and the scaler comes before the CSC unit.
  - In case of YUV4:2:2 input data with 90-/270-degree rotation, the data is preprocessed by duplicating the missing chrominance samples.
  - In case of YUV4:2:2 input data with 0-/180-degree rotation, the Chroma upsampling is performed in the scaler unit.

Table 10-30 lists the input formats supported by the video pipelines.

The video pipeline is enabled by setting the DISPC_VIDp_ATTRIBUTES[0] ENABLE bit to 0x1.

Figure 10-41. DISPC Configuration 1: Video Pipeline

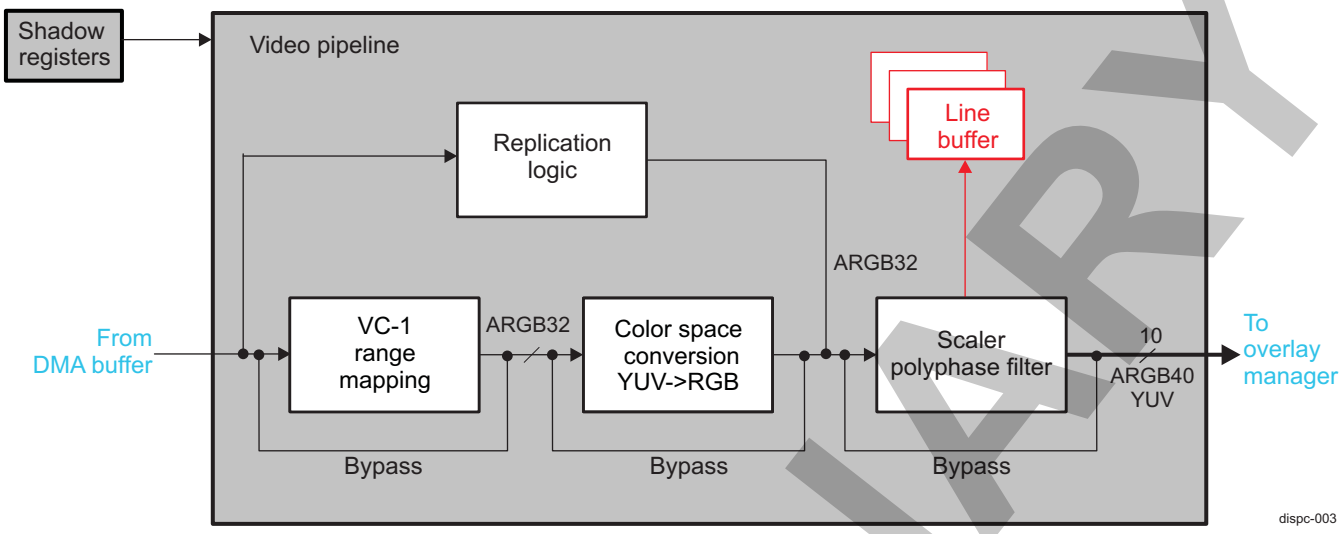

Figure 10-42. DISPC Configuration 2: Video Pipeline

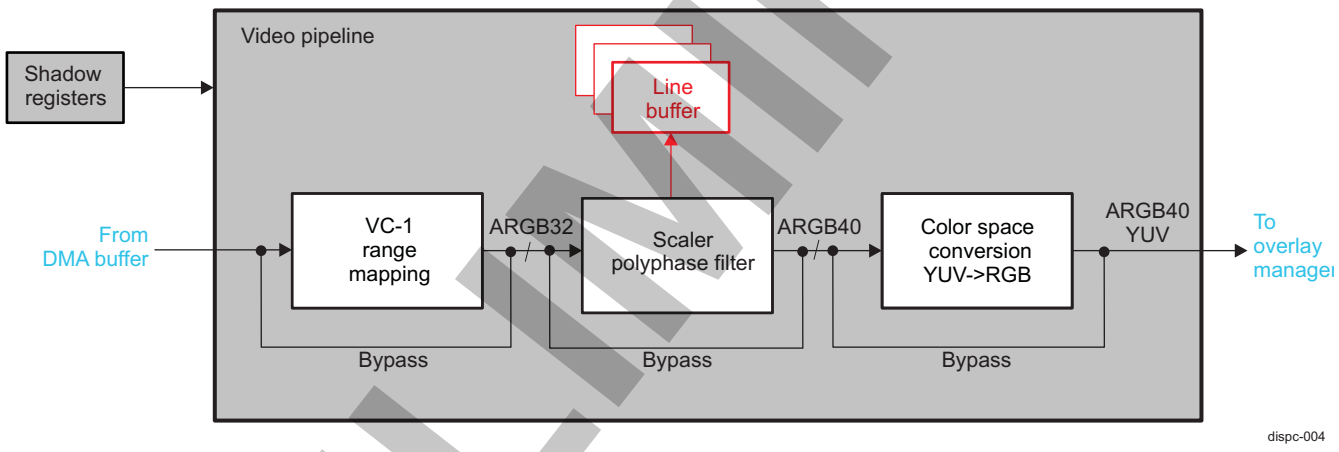

10.2.4.10.1 DISPC Replication Logic

The replication logic increases the color depth of the video-encoded pixels (from true color RGB 12, and 16 to 32 bpp) available only in configuration 1.

The expansion from 8- to 10-bit color component is done by the following units:

- The CSC unit, when the scaler is after the CSC module and when the vertical scaler is disabled
- The vertical scaler, when the scaler is after the CSC unit and enabled
- The replication bit module, when the CSC unit and scaler are disabled
- When the replication logic is enabled by setting the DISPC_VIDp_ATTRIBUTES[10] REPLICATIONENABLE bit to 0x1, the MSBs are copied to the missing LSBs. Table 10-33 describes the remapping of the RGB pixels into ARGB 32-bit values.

10.2.4.10.2 DISPC VC-1 Range Mapping Unit

The VC-1 range mapping unit is used when the video frame picture is decoded using a VC-1 codec by the video accelerator. It remaps the Y, Cb, and Cr components. The unit is used primarily for YUV4:2:0-NV12 and YUV4:2:0-NV21 pixel formats but also can be applied to YUV4:2:2 pixel formats (YUV2 and UYVY).

The VC-1 range mapping unit is enabled by setting the DISPC_VIDp_ATTRIBUTES2[0] VC1ENABLE bit to 0x1. The DISPC_VIDp_ATTRIBUTES2[3:1] VC1_RANGE_Y and DISPC_VIDp_ATTRIBUTES2[6:4] VC1_RANGE_CBCR bit fields are two 3-bit values programmed by the user and are independent for each video pipeline. The module is governed by the equations:

$Y_{out} = CLIP(((Y_{int} – 128) \times (VC1_RANGE_Y + 9) + 4) / 8) + 128)$

$C_b = CLIP(((C_b – 128) \times (VC1_RANGE_CBCR + 9) + 4) / 8) + 128)$

$C_r = CLIP(((C_r – 128) \times (VC1_RANGE_CBCR + 9) + 4) / 8) + 128)$

NOTE: The input and output pixel values are unsigned (Y, Cr, and Cb).

The function CLIP () clips to 0 or 255 when minimum or maximum, respectively, are reached; otherwise, the resulting output remains identical.

10.2.4.10.3 DISPC CSC Unit YUV to RGB

The CSC unit converts the video-encoded pixel values from YUV4:4:4 format into RGB24 or RGB30 format. The output format depends on the video pipeline configuration selected:

- Configuration 1: RGB24 output format, with 8-bit value per component: red, green, and blue
- Configuration 2: RGB30 output format, with 10-bit value per component: red, green, and blue

PRELIMINARY

In case of YUV4:2:0 or YUV4:2:2 formats, a chrominance resampling to YUV4:4:4 is required before converting the YUV into RGB values (see Section 10.2.4.10.3.1, *Chrominance Resampling*). YUV4:2:2 or YUV4:2:0 to YUV4:4:4 chrominance resampling is a preprocessing to the color space conversion.

Figure 10-43 through Figure 10-46 show the 3 × 3 11-bit coefficients used to convert from YUV4:4:4 into RGB24. The coefficients are set according to the standard used to encode the pixel data in YUV color space. Table 10-35 summarizes the coefficients with their respective bit fields.

Table 10-35. DISPC Color Space Conversion YUV to RGB Bit Field Setting

Coefficients	Bit Field Registers
R_Y	DISPC_VIDp_CONV_COEF0[10:0] RY
R_{Cr}	DISPC_VIDp_CONV_COEF0[26:16] RCR
R_{Cb}	DISPC_VIDp_CONV_COEF1[10:0] RCB
G_Y	DISPC_VIDp_CONV_COEF1[26:16] GY
G_{Cr}	DISPC_VIDp_CONV_COEF2[10:0] GCR
G_{Cb}	DISPC_VIDp_CONV_COEF2[26:16] GCB
B_Y	DISPC_VIDp_CONV_COEF3[10:0] BY
B_{Cr}	DISPC_VIDp_CONV_COEF3[26:16] BCR
B_{Cb}	DISPC_VIDp_CONV_COEF4[10:0] BCB

- For configuration 1 with an RGB24 output:

  If the active range for the luminance samples (Y) is [235:16] and [240:16] for the chrominance samples (Cb and Cr), the range selection is done by setting the DISPC_VIDp_ATTRIBUTES[11] FULLRANGE bit to 0x0. The values of R, G, and B output components are clipped to the range [255:0].

NOTE: The scaling and CSC clipping is set by the same bit, DISPC_VIDp_ATTRIBUTES[11] FULLRANGE.

Figure 10-43. DISPC YCbCr to RGB Registers (FULLRANGE = 0), 8-Bit Outputs

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{cr} & R_{cb} \\ G_Y & G_{cr} & G_{cb} \\ B_Y & B_{cr} & B_{cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} - 16 \\ Cr_{IN} - 128 \\ Cb_{IN} - 128 \end{bmatrix}$$

dispc-005

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [255:0], the range selection is done by setting the DISPC_VIDp_ATTRIBUTES[11] FULLRANGE bit to 0x1. The values of R, G, and B output components are clipped to the range [255:0].

Figure 10-44. DISPC YCbCr to RGB Registers (FULLRANGE = 1), 8-Bit Outputs

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{cr} & R_{cb} \\ G_Y & G_{cr} & G_{cb} \\ B_Y & B_{cr} & B_{cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} \\ Cr_{IN} - 128 \\ Cb_{IN} - 128 \end{bmatrix}$$

dispc-006

- For configuration 2 with an RGB30 output:

  If the active range for the luminance samples (Y) is [940:64] and [960:64] for the chrominance samples (Cb and Cr), the range selection is done by setting the DISPC_VIDp_ATTRIBUTES[11] FULLRANGE bit to 0x0. The values of R, G, and B output components are clipped to the range [1023:0].

NOTE: The scaling and CSC clipping is set by the same bit, DISPC_VIDp_ATTRIBUTES[11] FULLRANGE.

10.2.4.10.3.1 DISPC Chrominance Resampling

Two methods are supported to resample chrominance:

- Averaging of the chrominance is done by software, followed by hardware conversion when the video pipeline is in configuration 1.
- Filtering of the chrominance using the scaler unit (chrominance resampling and rescaling can be combined to support native rescaling of YUV format) when the video pipeline is in configuration 2.

To convert the YUV4:2:2 encoded pixel values into YUV4:4:4 format, the averaging of the chrominance technique can be used as shown in Figure 10-47. The missing chrominance samples (Cb and Cr) are interpolated using the average values of the two closest values on the same line (,) or are repeated from the second pixel in the same 32-bit container (see Figure 10-48). For the last pixel, the chrominance samples are duplicated using the values from the previous pixel; otherwise, the chrominance samples are averaged using the two adjacent values. Figure 10-49 shows the flow of the pixel.

Figure 10-47. DISPC Averaging of the Chrominance Formula

$$Cb_n(YCbCr\ 444) = \frac{Cb_{n-1}(YCbCr\ 422) + Cb_{n+1}(YCbCr\ 422)}{2}\ (\text{n odd})$$

$$Cr_n(YCbCr\ 444) = \frac{Cr_{n-1}(YCbCr\ 422) + Cr_{n+1}(YCbCr\ 422)}{2}\ (\text{n odd})$$

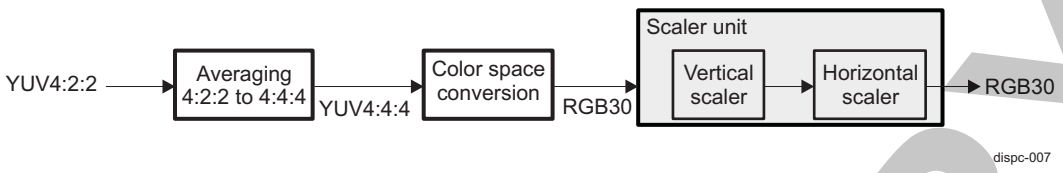
Figure 10-49. DISPC YUV4:2:2 to RGB30 Using Averaging of the Chrominance



The scaler unit can be used to resample the chrominance of YUV4:2:0 and YUV4:2:2, as shown in Figure 10-50 and Figure 10-51, respectively. The settings of the scaler unit to perform chrominance resampling are described in Section 10.2.4.10.4, *DISPC Scaler Unit*.

Figure 10-50. DISPC YUV4:2:0 to RGB30 Using Scaler Unit for Resampling Chrominance

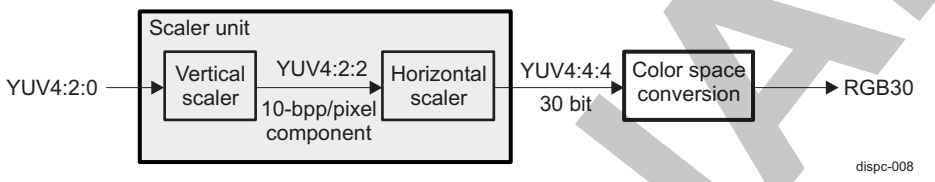


Figure 10-51. DISPC YUV4:2:2 to RGB30 Using Scaler Unit for Resampling Chrominance

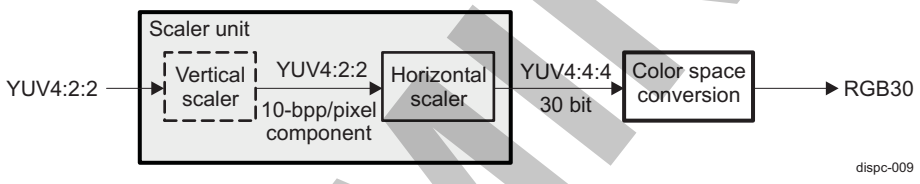


NOTE: If rotation must be supported, YUV4:2:2 and YUV4:2:0 (0-/180-degree rotation) chrominance resampling is done as shown in Figure 10-51 and Figure 10-50, respectively.
For YUV4:2:2 (90-/270-degree rotation) data are preprocessed to present YUV4:4:4 on the scaler input (duplication of the missing chroma), as shown in Figure 10-49.

10.2.4.10.4 DISPC Scaler Unit

All video formats are supported, including formats with alpha blending. Alpha blending is scaled with the same parameters as RGB color components. For the YUV formats, Y and Cb/Cr are processed independently. The filter is based on a finite impulse response (FIR) filter. The filtering can be used for different processing:

- Upsampling of the picture
- Downsampling of the picture
- Antiflicker reduction
- De-interlacing using bob algorithm
- Chrominance resampling in case of YUV data formats

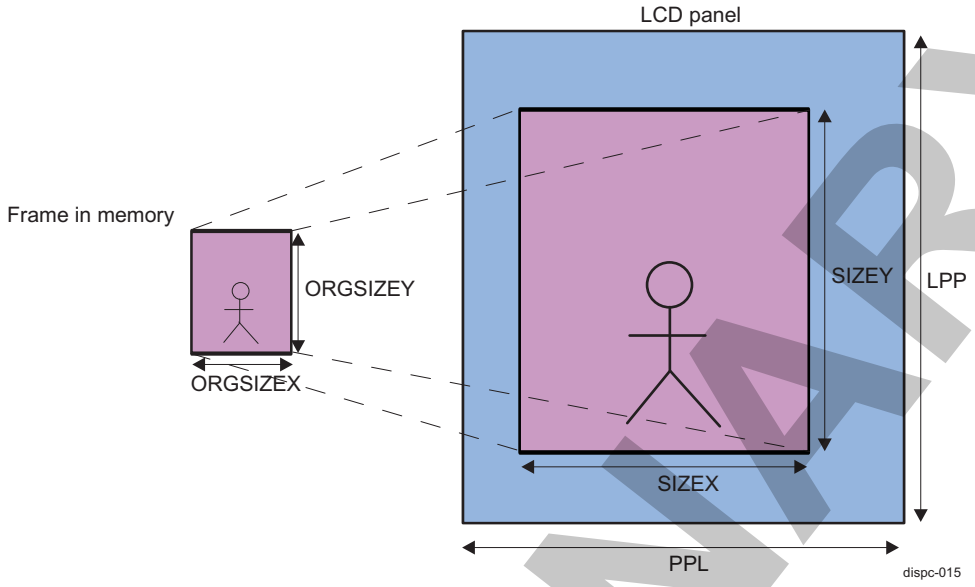
NOTE: The user must ensure that the resizing frame displays in the LCD/screen boundaries.

Figure 10-52 shows an example of video upsampling.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-52. DISPC Video Upsampling



The upsampling and downsampling filter is a polyphase filter with five taps and eight phases for the horizontal filter, and a programmable number of taps (three or five) and eight phases for vertical filter. The input buffer has five input memory lines. The following limitations must be considered:

- The upsampling ratio is up to x8.
- The downsampling ratio using 3-tap configuration is down to x0.5 for RGB format.
- The downsampling ratio using 5-tap configuration is down to x0.25 for RGB format.
- If the input format is changed from YUV4:2:2 to YUV4:2:0 (WB pipeline), the downsampling ratio is further reduced:
  - Using 5-tap configuration, the ratio is down to x0.5 for RGB format.
  - Using 3-tap configuration, no downscaling is available.

For vertical upsampling and downsampling in a 3-tap configuration, the equations are:

For RGB formats

$$A_{out}(n)=(\sum_{i=-1}^{i=1} C_{vi}(\Phi)*A_{in}(n+i))>>5$$

$$R_{out}(n)=(\sum_{i=-1}^{i=1} C_{vi}(\Phi)*R_{in}(n+i))>>5$$

$$G_{out}(n)=(\sum_{i=-1}^{i=1} C_{vi}(\Phi)*G_{in}(n+i))>>5$$

$$B_{out}(n)=(\sum_{i=-1}^{i=1} C_{vi}(\Phi)*B_{in}(n+i))>>5$$

For YUV formats

$$Y_{out}(n)=(\sum_{i=-1}^{i=1} C_{vi}(\Phi_y)*Y_{in}(n+i))>>5$$

$$Cr_{out}(n)=(\sum_{i=-1}^{i=1} C_{vci}(\Phi_c)*Cb_{in}(n+i))>>5$$

$$Cb_{out}(n)=(\sum_{i=-1}^{i=1} C_{vci}(\Phi_c)*Cr_{in}(n+i))>>5$$

dispc-013

(7)

For vertical upsampling and downsampling in a 5-tap configuration, the equations are:

For RGB formats

$$A_{out}(n)=(\sum_{i=-2}^{i=2} C_{vi}(\Phi)*A_{in}(n+i))>>5$$

$$R_{out}(n)=(\sum_{i=-2}^{i=2} C_{vi}(\Phi)*R_{in}(n+i))>>5$$

$$G_{out}(n)=(\sum_{i=-2}^{i=2} C_{vi}(\Phi)*G_{in}(n+i))>>5$$

$$B_{out}(n)=(\sum_{i=-2}^{i=2} C_{vi}(\Phi)*B_{in}(n+i))>>5$$

For YUV formats

$$Y_{out}(n)=(\sum_{i=-2}^{i=2} C_{vi}(\Phi_y)*Y_{in}(n+i))>>5$$

$$Cb_{out}(n)=(\sum_{i=-2}^{i=2} C_{vci}(\Phi_c)*Cb_{in}(n+i))>>5$$

$$Cr_{out}(n)=(\sum_{i=-2}^{i=2} C_{vci}(\Phi_c)*Cr_{in}(n+i))>>5$$

dispc-012

PRELIMINARY

For horizontal upsampling and downsampling in a 5-tap configuration, the equations are:

For RGB formats

$$A_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hi}(\Phi)*A_{in}(n+i)\right)>>7$$

$$R_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hi}(\Phi)*R_{in}(n+i)\right)>>7$$

$$G_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hi}(\Phi)*G_{in}(n+i)\right)>>7$$

$$B_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hi}(\Phi)*B_{in}(n+i)\right)>>7$$

For YUV formats

$$Y_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hi}(\Phi_y)*Y_{in}(n+i)\right)>>7$$

$$Cb_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hci}(\Phi_c)*Cb_{in}(n+i)\right)>>7$$

$$Cr_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hci}(\Phi_c)*Cr_{in}(n+i)\right)>>7$$

dispc-014 (9)

NOTE: The pixel (n + 1) is the previous pixel with respect to pixel (n). The line (n + 1) is the previous line with respect to line (n).

The coefficients Ci() depend on the phase between input and output pixels.

NOTE: The coefficients are different for Y and Cr, Cb filtering because the calculations are independent due to the chrominance resampling for YUV4:2:2 and YUV4:2:0.

First, the vertical filter is applied to the encoded input pixel data, and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. The vertical input of the filter consists of five lines of 2048 × 32 bits for both 3-tap and 5-tap configurations (see Table 10-36).

Table 10-36. DISPC Line Buffer Width for Scaler Unit

Vertical Taps	Maximum Input Width (Pixels)
3, 5	2048 × 32 bits

At the beginning of frame scaling processing, the first line is duplicated to fill the first two lines in 3-tap configuration and the first three lines in 5-tap configuration.

At the end of frame scaling processing, the last line is duplicated if the scaling logic requires loading more lines and the last line has been reached.

The programmable coefficients of the polyphase filters are signed 8-bit values (except for the central coefficient, which is unsigned). The video scalers have an 8-bit input and a 10-bit output. The vertical scaling changes the 8-bit input into a 10-bit clipped output and the horizontal scaling takes the 10-bit input.

Figure 10-53 and Figure 10-54 show the scaler macro-architecture for the component A, R, G, B, and Y. Figure 10-55 and Figure 10-56 show the scaler macro-architecture for component Cr and Cb.

The scaling output can be clipped to an output range of [1023:0] or [960:64] by configuring the DISPC_VIDp_ATTRIBUTES[11] FULLRANGE bit.

NOTE: The scaling and CSC clipping is set by the same bit, DISPC_VIDp_ATTRIBUTES[11] FULLRANGE.

The VID scaler unit vertical or/and horizontal sampling is defined by setting/resetting the DISPC_VIDp_ATTRIBUTES[6:5] RESIZEENABLE bit field.

A set of configurations must be valid before enabling the video upsampling and downsampling block.

The following fields define the configuration of the video upsampling downsampling block for VIDp:

- Vertical upsampling and downsampling increments the value of the DISPC_VIDp_FIR[28:16] FIRVINC bit field. The unsigned integer value range is [4096:1]. Software calculates the value using the following equation:

$$FIRVINC = 1024 \times \left(\frac{MEMSIZEY}{SIZEY} \right)$$

dispc-066 (10)

NOTE:

- If the value of the DISPC_VIDp_FIR[28:16] FIRVINC bit field is greater than 4096, it is clipped to 4096.
- If the ISPC_VIDp_SIZE[27:16] SIZEY bit field equals 0x1, SIZEY is replaced by 0x2 in the previous equation.
- The values of the DISPC_VIDp_PICTURE_SIZE[27:16] MEMSIZEY and DISPC_VIDp_SIZE[27:16] SIZEY bit fields must be programmed with the value desired minus 1.

- Horizontal upsampling and downsampling increments the value of the DISPC_VIDp_FIR[12:0] FIRHINC bit field. The unsigned integer value range is [4096:1]. Software calculates the value using the following equation:

$$FIRHINC = 1024 \times \left(\frac{MEMSIZEX}{SIZEX} \right)$$

dispc-067 (11)

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE:

- If the value of the DISPC_VIDp_FIR[12:0] FIRHINC bit field is greater than 4096, it is clipped to 4096.
- If the DISPC_VIDp_SIZE[11:0] SIZEX bit field equals 1, SIZEX is replaced by 2 in the previous equation.
- The values of the DISPC_VIDp_PICTURE_SIZE[10:0] MEMSIZEX and DISPC_VIDp_SIZE[11:0] SIZEX bit fields must be programmed with the value desired minus 1.

- Vertical up/downsampling accumulator value DISPC_VIDp_ACCU_j[26:16] VERTICALACCU bit field: The signed integer value range is [–1024:1023]. The accumulator value indicates on which phase the vertical filtering starts. The register DISPC_VIDp_ACCU_0 is used for progressive output and for interlace output; the DISPC_VIDp_ACCU_0 and DISPC_VIDp_ACCU_1 registers are used. Similarly, DISPC_VIDp_ACCU2_0 and DISPC_VIDp_ACCU2_1 are used in progressive or interlace output to set the accumulator value of the Cb and Cr components when scaling YUV format.
- Vertical upsampling and downsampling line buffer configuration DISPC_VIDp_ATTRIBUTES[21] VERTICALTAPS bit: The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used.
- Horizontal upsampling and downsampling accumulator value DISPC_VIDp_ACCU_j[10:0] HORIZONTALACCU bit field: The signed integer value range is [–1024:1023]. The accumulator value indicates on which phase the horizontal filtering starts. The register DISPC_VIDp_ACCU_0 is used for progressive output and for interlace output; the DISPC_VIDp_ACCU_0 and DISPC_VIDp_ACCU_1 registers are used. Similarly, DISPC_VIDp_ACCU2_0 and DISPC_VIDp_ACCU2_1 are used in progressive or interlace output to set the accumulator value of the Cb and Cr components when scaling YUV format.

Table 10-39 lists the DISPC vertical and horizonatal accumulator values and phases.

Table 10-39. DISPC Vertical and Horizontal Accumulator Phase

Accumulator Value	Phases f
0	0
128 or –896	1
256 or –768	2
384 or –640	3
512 or –512	4
640 or –384	5
768 or –256	6
896 or –128	7

- Vertical upsampling and downsampling coefficients:
  - The 3-tap vertical upsampling and downsampling coefficients are defined in the DISPC_VIDp_FIR_COEF_HV_i registers. There are 8 registers for the 8 phases with 3 coefficients for each, or a total of 24 programmable coefficients for the vertical upsampling and downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one).
  - The 5-tap vertical upsampling and downsampling coefficients: Two extra-tap vertical upsampling and downsampling coefficients are defined in the DISPC_VIDp_FIR_COEF_V_i registers. There are 8 registers for the 8 phases with 2 coefficients for each of them, so a total of 16 programmable coefficients for the vertical upsampling downsampling block are used in addition to the 3-tap registers previously defined.

  Four YUV vertical upsampling and downsampling coefficients are set in DISPC_VIDp_FIR_COEF_HV2_i and DISPC_VIDp_FIR_COEF_V2_i registers. Table 10-37 and Table 10-38 summarize all coefficients and their respective registers.
- Horizontal upsampling and downsampling coefficients:

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

– The DISPC_VIDp_FIR_COEF_H_i and DISPC_VIDp_FIR_COEF_HV_i registers define the 5-tap horizontal up/downsampling coefficients. Each DISPC_VIDp_FIR_COEF_H_i register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one). Each DISPC_VIDp_FIR_COEF_HV_i register contains one 8-bit signed coefficient. A total of 40 programmable coefficients for the horizontal upsampling and downsampling block are used.

Four YUV horizontal upsampling and downsampling coefficients are set in the DISPC_VIDp_FIR_COEF_HV2_i and DISPC_VIDp_FIR_COEF_H2_i registers. Table 10-37 and Table 10-38 summarize all coefficients and their respective registers.

Section 10.2.4.10.4.3, *DISPC Filter Coefficients*, provides reference tables with example values for filter coefficients.

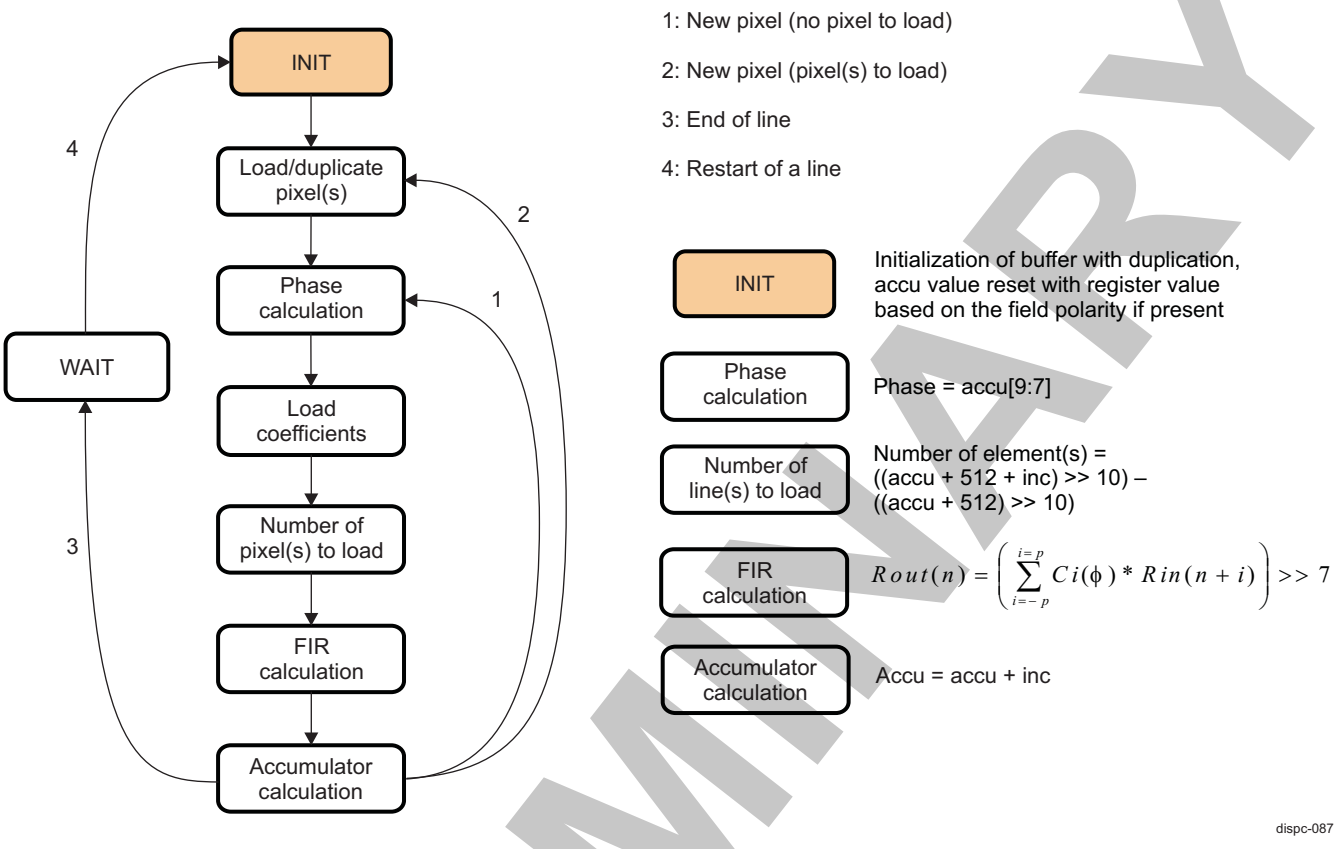
Figure 10-58. DISPC Horizontal Up/Downsampling Algorithm



10.2.4.10.4.2 DISPC Scaling limitations

Table 10-40 lists the minimum ratio between the pixel clock frequency (DSS_DISPC_LCDn_PCLK) and the functional clock (F_CLK) in the input pixel format when using the scaler unit. DSS_DISPC_LCDn_PCLK and F_CLK are asynchronous. For each LCD output, a dedicated LCD clock is programmable with the LCD and PCD divisor values in DISPC_DIVISORo[23:16][7:0].

NOTE: The F_CLK is derived from DSS_FCLK through the LCD divisor.

NOTE: The downscaling ratio is not an integer, it is the ratio F_CLK / DSS_DISPC_LCDn_PCLK, meaning if the ratio is 2.7, then the downscaling ratio is 2.7 and not 2.

Table 10-40. DISPC Pixel Clock Frequency Limitations (Any Pixel Format) – Active Matrix Display

F_CLK/DSS_DISPC_LCDn_PCLK Minimum Ratio	Horizontal Resampling				
	Off	Up	1:1–1:2	1:2–1:3	1:3–1:4
	2 or 1[(1)]	2 or 1[(1)])	2	3	4

(1) The minimum ratio can be 1 if the data are output on the rising edge of the PCLK (DISPC_POL_FREQo.IPC = 0); otherwise, the minimum ratio must be 2.

10.2.4.10.4.3 DISPC Filter Coefficients

NOTE: This section provides reference tables with filter-coefficient example values obtained using the Lanczos window function.

All scaler coefficients and their corresponding registers are summarized in Table 10-37 and Table 10-38.

Table 10-41 gives the 40 coefficients for the 8 phases of 5-tap configuration for different values of the downsampling factor M.

Table 10-42 gives the 24 coefficients for the 8 phases of 3-tap configuration for different values of the downsampling factor M.

The selection of coefficients from Table 10-41 and Table 10-42 is based on the target scaling ratio:

- Dividing the scaling ratio by 8 gives the ideal FIR filter cut-off frequency (Fc) and matching decimation factor (M). For example, a scaling ratio of ½ gives an ideal cut-off frequency of 1/16 (in other words, the decimation factor M = 16).
- If a sharper image result is required, then the coefficients corresponding to lower M value than calculated should be selected. For example, a scaling ratio of 1/3 gives M = 24. For sharper image result, the coefficients for M = 22 should be selected. This is the preferred method when using the DISPC scaler unit.
- If a smoother image result is required, then the coefficients corresponding to higher M value than calculated should be selected. In the same example as above, a scaling ratio of 1/3 gives M = 24. For smoother image result, the coefficients for M = 26 should be selected.
- The coefficients for M = 8 could be used for any up-scaling ratio, but are preferred for up-scaling ratios up to 2.
- For up-scaling ratio > 2, in order to avoid possible blockiness and outlines around the image when using filter coefficients for M = 8, the following could be considered:
  - For calculated M = 3, the coefficient values for M = 11 should be used.
  - For calculated M = 2, the coefficient values for M = 16 should be used.
  - For calculated M = 0 to 1, the coefficient values for M = 19 should be used.

Table 10-41. Filter Coefficients (Five Taps)

Downsampling Factor M (range)	Coefficients	Phases							
		0	1	2	3	4	5	6	7
4-8	C(2)	0	1	2	1	–14	–10	–6	–2
	C(1)	0	–10	–15	–16	78	55	33	14
	C(0)	128	125	114	98	78	98	114	125

10.2.4.11 DISPC Write-Back Pipeline

The write-back pipeline is used to store in the system memory the capture of the overlay output or the output of one of the pipelines. The WB pipeline consists of a CSC unit, a scaler unit, and an RGB truncation logic. Because the overlay works on ARGB32-8888 format and the video accelerator works on YUV format, the color space conversion from RGB to YUV is used to directly output to memory the format that can be encoded with no extra processing.

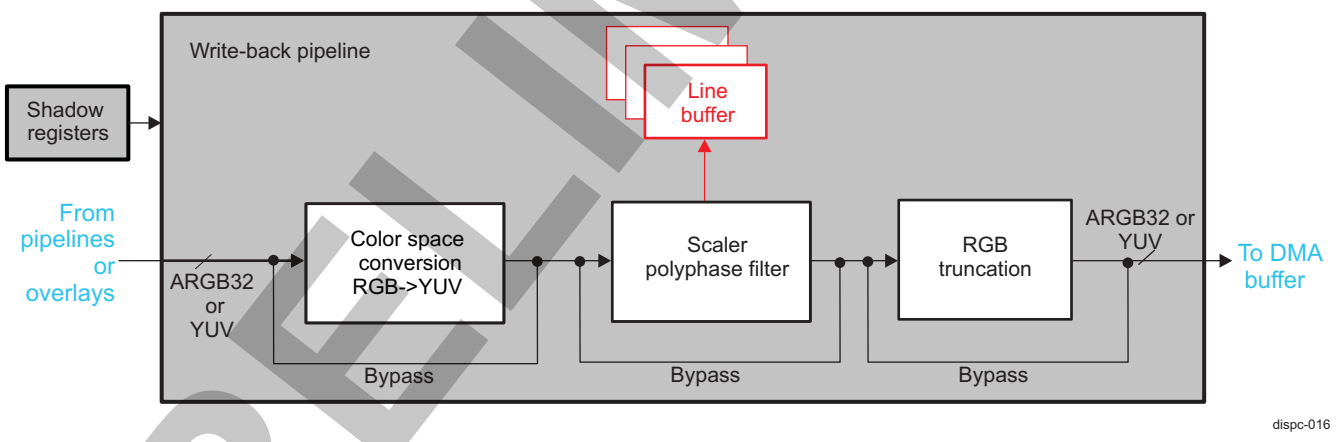
The write-back pipeline is connected to all the pipeline outputs (GFX, VD1, VID2, and VID3 pipelines) and to the output of the three overlay managers (LCD1, LCD2, LCD3, and TV). The input is selected by setting the DISPC_WB_ATTRIBUTES[18:16] CHANNELIN bit field, and the capture frame rate is set in the DISPC_WB_ATTRIBUTES[26:24] CAPTUREMODE bit field.

Because the output format of the TV overlay manager is ARGB40, the graphics pipeline output is ARGB40, the video pipeline outputs are YUV4:2:2, YUV4:2:0, or ARGB40, and the WB input is ARGB32, the WB input does not consider the 2 LSBs of each ARGB component.

The WB pipeline is enabled by setting the DISPC_WB_ATTRIBUTES[0] ENABLE bit to 0x1.

Figure 10-59 shows the graphics pipeline.

Figure 10-59. DISPC Write-Back Pipeline



10.2.4.11.1 DISPC CSC Unit RGB to YUV

The RGB-to-YUV CSC unit converts the encoded pixel values from RGB24 into YUV4:4:4 format. For YUV4:2:0 or YUV4:2:2 formats, a chrominance sub-sampling is required after converting the RGB into YUV values. Because of the subsampling, the following limitations must be considered:

- When converting RGB into YUV4:2:0 NV12 format:
  - Maximum horizontal downscale = x0.5
  - Maximum vertical downscale = x0.5
- When converting RGB into YUV4:2:2 format:
  - Maximum horizontal downscale = x0.5
  - Maximum vertical downscale = x0.25

PRELIMINARY

Figure 10-60 and Figure 10-61 show the 3 × 3 11-bit coefficients used to convert from RGB24 into YUV4:4:4. The user sets the coefficients according to the standard used to encode the pixel data in YUV color space. Table 10-43 lists the coefficients with their respective bit fields.

Table 10-43. DISPC CSC RGB to YUV Bit Field Setting

Coefficients	Bit Fields
Y_R	DISPC_WB_CONV_COEF0[10:0] YR
Y_G	DISPC_WB_CONV_COEF0[26:16] YG
Y_B	DISPC_WB_CONV_COEF1[10:0] YB
Cr_R	DISPC_WB_CONV_COEF1[26:16] CRR
Cr_G	DISPC_WB_CONV_COEF2[10:0] CRG
Cr_B	DISPC_WB_CONV_COEF2[26:16] CRB
Cb_R	DISPC_WB_CONV_COEF3[10:0] CBR
Cb_G	DISPC_WB_CONV_COEF3[26:16] CBG
Cb_B	DISPC_WB_CONV_COEF4[10:0] CBB

If the active range for the luminance samples (Y) is [16:235] and [16:240] for the chrominance samples (Cb and Cr), the values of Y, Cb, and Cr output components are clipped to the range [0:255]. The range selection is done by setting the DISPC_WB_ATTRIBUTES[11] FULLRANGE bit to 0x0.

Figure 10-60. DISPC RGB to YCbCr (FULLRANGE = 0)

$$\begin{bmatrix} Y_{OUT} \\ Cb_{OUT} \\ Cr_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cb_R & Cb_G & Cb_B \\ Cr_R & Cr_G & Cr_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 16 \\ 128 \\ 128 \end{bmatrix}$$

dispc-017

If the active range for the luminance samples (Y) and or the chrominance samples (Cb and Cr)is [0:255], the values of Y, Cb, and Cr output components are clipped to the range [0:255]. The range selection is done by setting the DISPC_WB_ATTRIBUTES[11] FULLRANGE bit to 0x1.

Figure 10-61. DISPC RGB to YCbCr (FULLRANGE = 1)

$$\begin{bmatrix} Y_{OUT} \\ Cb_{OUT} \\ Cr_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cb_R & Cb_G & Cb_B \\ Cr_R & Cr_G & Cr_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 0 \\ 128 \\ 128 \end{bmatrix}$$

dispc-018

10.2.4.11.2 DISPC Scaler Unit

The functional aspect of the WB pipeline scaler unit is identical to the video pipeline scaler unit (see Section 10.2.4.10.4, *DISPC Scaler Unit*), except in the output width when scaling ARGB components. The resulting output format is ARGB32 instead of ARGB40.In addition, the scaling limitations described in Section 10.2.4.10.4.2 are relevant only to the video pipelines scaler units. In WB memory-to-memory mode there are no limitations on the F_CLK/DSS_DISPC_LCDn_PCLK ratio for horizontal resampling.

The programmable coefficients of the polyphase filters are signed 8-bit values (except for the central coefficient, which is unsigned). The WB scaler component has an 8-bit input and an 8-bit output.

Figure 10-62 and Figure 10-63 show the scaler macro-architecture for the component A, R, G, B, and Y. Figure 10-64 and Figure 10-65 show the scaler macro-architecture for component Cr and Cb.

The scaling output can be clipped to an output range of [0:255] or [16:240] by configuring the DISPC_WB_ATTRIBUTES[11] FULLRANGE bit.

	Chc(2)		FIRHC0	DISPC_WB_FIR_COEF_H2_i

The WB scaler unit vertical or/and horizontal sampling is defined by setting/resetting the DISPC_WB_ATTRIBUTES[6:5] RESIZEENABLE bit field.

A set of configuration must be valid before enabling the video up/downsampling block.

The following fields define the configuration of the video up/downsampling block for WB:

- Vertical up/downsampling increments the value of the DISPC_WB_FIR[28:16] FIRVINC bit field. The unsigned integer value range is [1:4096]. Software calculates the value using the following equation:

$$FIRVINC = 1024 \times \left(\frac{MEMSIZEY}{SIZEY} \right)$$

dispc-066 (12)

NOTE:

- If the value of the DISPC_WB_FIR[28:16] FIRVINC bit field is greater than 4096, it is clipped to 4096.
- If the DISPC_WB_SIZE[27:16] SIZEY bit field equals 0x1, SIZEY is replaced by 0x2 in the previous equation.
- The values of the DISPC_WB_PICTURE_SIZE[27:16] MEMSIZEY and DISPC_WB_SIZE[27:16] SIZEY bit fields must be programmed with the value desired minus 1.

- Horizontal up/downsampling increments the value of the DISPC_WB_FIR[12:0] FIRHINC bit field: The unsigned integer value range is [1:4096]. Software calculates the value using the following equation:

$$FIRHINC = 1024 \times \left(\frac{MEMSIZEX}{SIZEX} \right)$$

dispc-067 (13)

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE:

- If the value of the DISPC_WB_FIR[12:0] FIRHINC bit field is greater than 4096, it is clipped to 4096.
- If the DISPC_WB_SIZE[10:0] SIZEX bit field equals 1, the DISPC_WB_SIZE[10:0] SIZEX bit field is replaced by 2 in the previous equation.
- The value of the DISPC_WB_PICTURE_SIZE[10:0] MEMSIZEX and DISPC_WB_SIZE[10:0] SIZEX bit fields must be programmed with the value desired minus 1.

- Vertical up/downsampling accumulator value DISPC_WB_ACCU_j[26:16] VERTICALACCU bit field: The signed integer value range is [–1024:1023]. The accumulator value indicates on which phase the vertical filtering starts. The register DISPC_WB_ACCU_0 is used for progressive output and for interlace output the DISPC_WB_ACCU_0 and DISPC_WB_ACCU_1 registers are used. Similarly, DISPC_WB_ACCU2_0 and DISPC_WB_ACCU2_1 are used in progressive or interlace output to set the accumulator value of the Cb and Cr components when scaling YUV format.
- Vertical up/downsampling line buffer configuration DISPC_WB_ATTRIBUTES[21] VERTICALTAPS bit: The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used.
- Horizontal up/downsampling accumulator value DISPC_WB_ACCU_j[10:0] HORIZONTALACCU bit field: The signed integer value range is [–1024:1023]. The accumulator value indicates on which phase the horizontal filtering starts. The register DISPC_WB_ACCU_0 is used for progressive output and for interlace output the DISPC_WB_ACCU_0 and DISPC_WB_ACCU_1 registers are used. Similarly, DISPC_WB_ACCU2_0 and DISPC_WB_ACCU2_1 are used in progressive or interlace output to set the accumulator value of Cb and Cr components when scaling YUV format.

Table 10-46 lists the DISPC vertical and horizontal accumulator values and phases.

Table 10-46. DISPC Vertical/Horizontal Accumulator Phase

Accumulator Value	Phases f
0	0
128 or –896	1
256 or –768	2
384 or –640	3
512 or –512	4
640 or –384	5
768 or –256	6
896 or –128	7

- Vertical up/downsampling coefficients:
  - The 3-tap vertical up/downsampling coefficients are defined in the DISPC_WB_FIR_COEF_HV_i registers. There are 8 registers for the 8 phases with 3 coefficients for each, or a total of 24 programmable coefficients for the vertical up/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one).
  - The 5-tap vertical up/downsampling coefficients: Two extra-tap vertical up/downsampling coefficients are defined in the DISPC_WB_FIR_COEF_V_i registers. There are 8 registers for the 8 phases with 2 coefficients for each of them, so a total of 16 programmable coefficients for the vertical up/downsampling block are used in addition to the 3-tap registers previously defined.

  Four YUV vertical up/downsampling coefficients are set in the DISPC_WB_FIR_COEF_HV2_i and DISPC_WB_FIR_COEF_V2_i registers. Table 10-44 and Table 10-45 summarize all coefficients and their respective registers.
- Horizontal up/downsampling coefficients:
  - The DISPC_WB_FIR_COEF_H_i and DISPC_WB_FIR_COEF_HV_i registers define the 5-tap horizontal up/downsampling coefficients. Each DISPC_WB_FIR_COEF_H_i register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one). Each

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

DISPC_WB_FIR_COEF_HV_i register contains one 8-bit signed coefficient. A total of 40 programmable coefficients for the horizontal up/downsampling block are used.

Four YUV horizontal up/downsampling coefficients are set in the DISPC_WB_FIR_COEF_HV2_i and DISPC_WB_FIR_COEF_H2_i registers. Table 10-44 and Table 10-45 summarize all coefficients and their respective registers.

NOTE: The values and selection criteria for programmable filter coefficients of the WB scaler unit is the same as for VID pipelines (see Section 10.2.4.10.4.3, *DISPC Filter Coefficients*).

10.2.4.11.3 DISPC RGB Truncation Logic

Truncation logic is used to convert a pixel from ARGB 32-bit format into a lower color depth: 12- or 16-bit format based. Setting the DISPC_WB_ATTRIBUTES[10] TRUNCATIONENABLE bit to 0x1 enables the truncation to the pixel format defined by the DISPC_WB_ATTRIBUTES[4:1] FORMAT bit field. The truncation is done by removing the necessary LSB of each component to match the output format. Table 10-47 describes the truncation done on each component of the pixel.

Table 10-47. DISPC Truncation Logic

	A[7:0]	R[7:0]	G[7:0]	B[7:0]
Output Formats	**MSB LSB**	**MSB LSB**	**MSB LSB**	**MSB LSB**
xRGB12-4444	Ignored	R[7:4]	G[7:4]	B[7:4]
RGBx12-4444	Ignored	R[7:4]	G[7:4]	B[7:4]
RGB16-565	Ignored	R[7:3]	G[7:2]	B[7:3]
xRGB16-1555	Ignored	R[7:3]	G[7:3]	B[7:3]
ARGB16-4444	A[7:4]	R[7:4]	G[7:4]	B[7:4]
RGBA16-4444	A[7:4]	R[7:4]	G[7:4]	B[7:4]
ARGB16-1555	A[7]	R[7:3]	G[7:3]	B[7:3]

NOTE: If there is no alpha field in the pixel format description, 0s or 1s must fill the container. 0s must be used for transparent and 1s for opaque. For example, in xRGB12 pixel format, the upper 4 bits are set to 0s because the RGB value is only 12 bits inside a 16-bit container.

10.2.4.12 DISPC LCD Outputs

The LCD1, LCD2, LCD3 output paths consist of several processing blocks (see Figure 10-66):

- Overlay manager
- Gamma correction unit
- Color phase rotation (CPR) (also used for RGB-to-YUV conversion)
- Active matrix dithering with TDM
- Synchronization buffer
- Timing generator

The display subsystem supports active matrix technologie (monochrome and color modes):

- Active matrix displays: the configuration of colors depends on the color depth:
  - 24 bpp supports 16,777,216 colors.
  - 18 bpp supports 262,144 colors.
  - 16 bpp supports 65,536 colors.
  - 12 bpp supports 4096 colors.

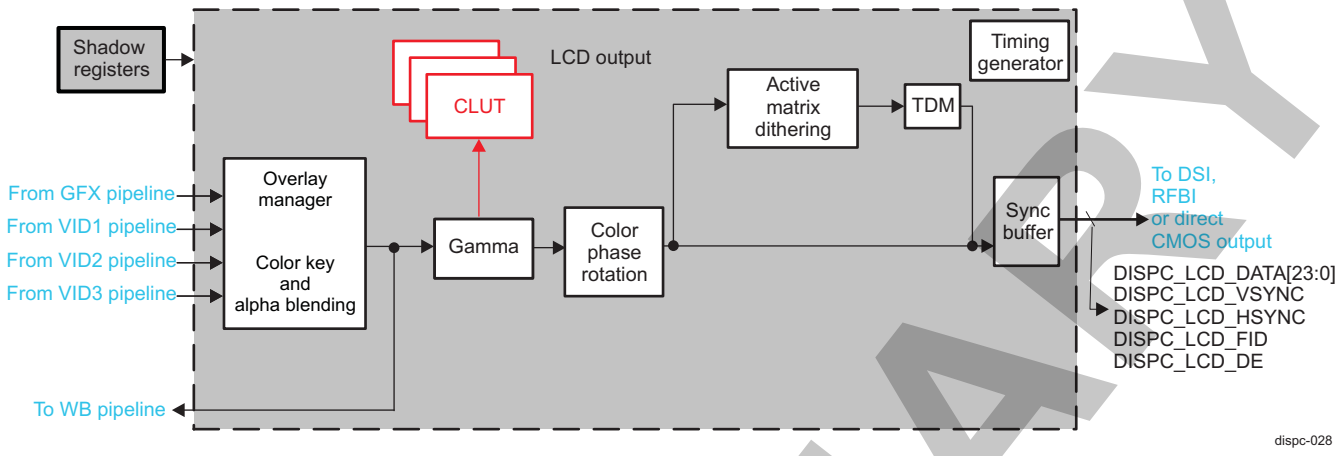
Figure 10-66. DISPC LCD Output Architecture



10.2.4.12.1 DISPC Overlay Manager

The overlay mechanism consists of displaying more than one layer (GFX, VID1 to VID3 layers) using:

- A priority rule based on a Z-order: Application can set the ordering layer of the frames.
- Transparency color keys: Destination and source transparency color keys can be set.
- Alpha blending values: Using the A component of a pixel or a blending set by the user for a layer, a level of transparency can be determined.

Each pipeline (GFX, VID1, VID2, and VID3) is assigned to a single overlay and, as a consequence, to a single display controller output, LCD1, LCD2, LCD3, TV, or WB pipeline. An overlay manager can be connected to all four pipelines outputs simultaneously. The pipeline output is directed using the DISPC_GFX_ATTRIBUTES[8] CHANNELOUT bit and the DISPC_VIDp_ATTRIBUTES[31:30] CHANNELOUT2 bit field. Table 10-48 summarizes the bit field settings to direct a pipeline to an LCD/TV or WB output. The default value directs all pipelines to LCD1.

Table 10-48. DISPC Pipeline Connection to LCD, TV, or WB Output

	DISPC_GFX_ATTRIBUTES/DISPC_VIDp_ATTRIBUTES	
Overlay Manager/Output	**CHANNELOUT Bit**	**CHANNELOUT2 Bit Field**
LCD1	0x0	0x0
LCD2	0x0	0x1
LCD3	0x0	0x2
WB	0x0	0x3
TV	0x1	0x0 (See the following note.)

NOTE: When CHANNELOUT = 0x1, the settings CHANNELOUT2 = 0x0, 0x1, 0x2, and 0x3 are reserved.

The output of each LCD overlay manager is connected to CPR block through the palette unit in the case of gamma correction.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE:

- When the pixel format is ARGB or RGBA, the color key match logic uses only the RGB value defined by ARGB or RGBA. The alpha blending factor is ignored.
- For LCD1 output, the same CLUT is used for BITMAP support by the graphics pipeline and for gamma correction. In case of BITMAP format for graphics, gamma correction is not available on the primary LCD output.

10.2.4.12.1.1 DISPC Priority Rule

The overlay manager is configured using the Z-order parameter. The Z-order value defined for each pipeline indicates the visibility order to the window on the screen. If the Z-order value of window A is lower than the Z-order to layer B, layer A is displayed below layer B. The transparency color keys and the alpha blending factors are then used to blend the layers together (see Section 10.2.4.12.1.2, *DISPC ALPHA Blender*, and Section 10.2.4.12.1.3, *DISPC Transparency Color Keys*). The Z-order is enabled by setting the DISPC_GFX_ATTRIBUTES[25] ZORDERENABLE bit or the DISPC_VIDp_ATTRIBUTES[25] ZORDERENABLE bit to 0x1 and by defining the Z-order in the DISPC_GFX_ATTRIBUTES[27:26] and DISPC_VIDp_ATTRIBUTES[27:26] ZORDER bit fields. Table 10-49 summarizes the register settings to enable and set the Z-order of a pipeline. Table 10-49 shows the default Z-order values when LCDALPHABLENDERENABLE and ZORDERENABLE are disabled.

Table 10-49. DISPC Z-Order Register Settings and Default Configuration

Pipeline	LCDALPHA BLENDERENABLE[1]	ZORDERENABLE	ZORDER	Resulting Z-Order Number
GFX	0	0	Don't care	0
	0	1	ZORDER	ZORDER
	1	Don't care	Don't care	3
VID1	0	0	Don't care	1
	0	1	ZORDER	ZORDER
	1	Don't care	Don't care	0
VID2	0	0	Don't care	2
	0	1	ZORDER	ZORDER
	1	Don't care	Don't care	1
VID3	0	0	Don't care	3
	0	1	ZORDER	ZORDER
	1	Don't care	Don't care	2

(1) Applies only to LCD1

Figure 10-67 shows the architecture of the priority rule.

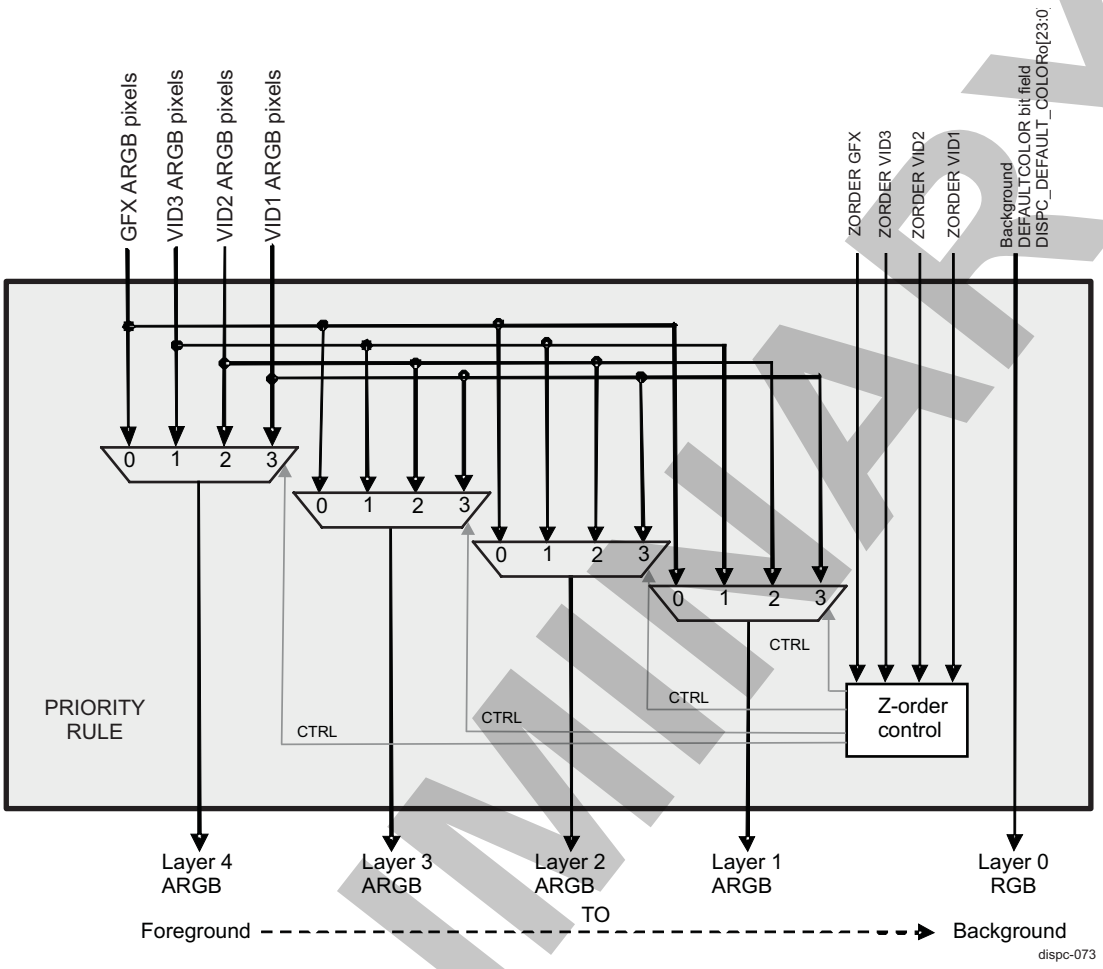
NOTE:

- If ZORDERENABLE = 1, each Z-order must be different for each active pipeline. It is not possible to use the same value for more than one pipeline.
- Two modes are maintained for backward compatibility with legacy devices:
  - LCDALPHABLENDERENABLE = 0 and ZORDERENABLE = 0 equivalent to the normal mode overlay settings
  - LCDALPHABLENDERENABLE = 1 equivalent to the alpha mode overlay settings
- When OMAP3430 backward compatibility mode is to be used, the following must be considered:
  - If Z-order is disabled for the VID1 and VID2 pipelines, the pipeline data is output on the LCD1/LCD2/TV overlay.
  - If Z-order is disabled for the VID3 pipeline, the pipeline data is output only on the LCD2 overlay.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-67. DISPC Priority Rule Architecture



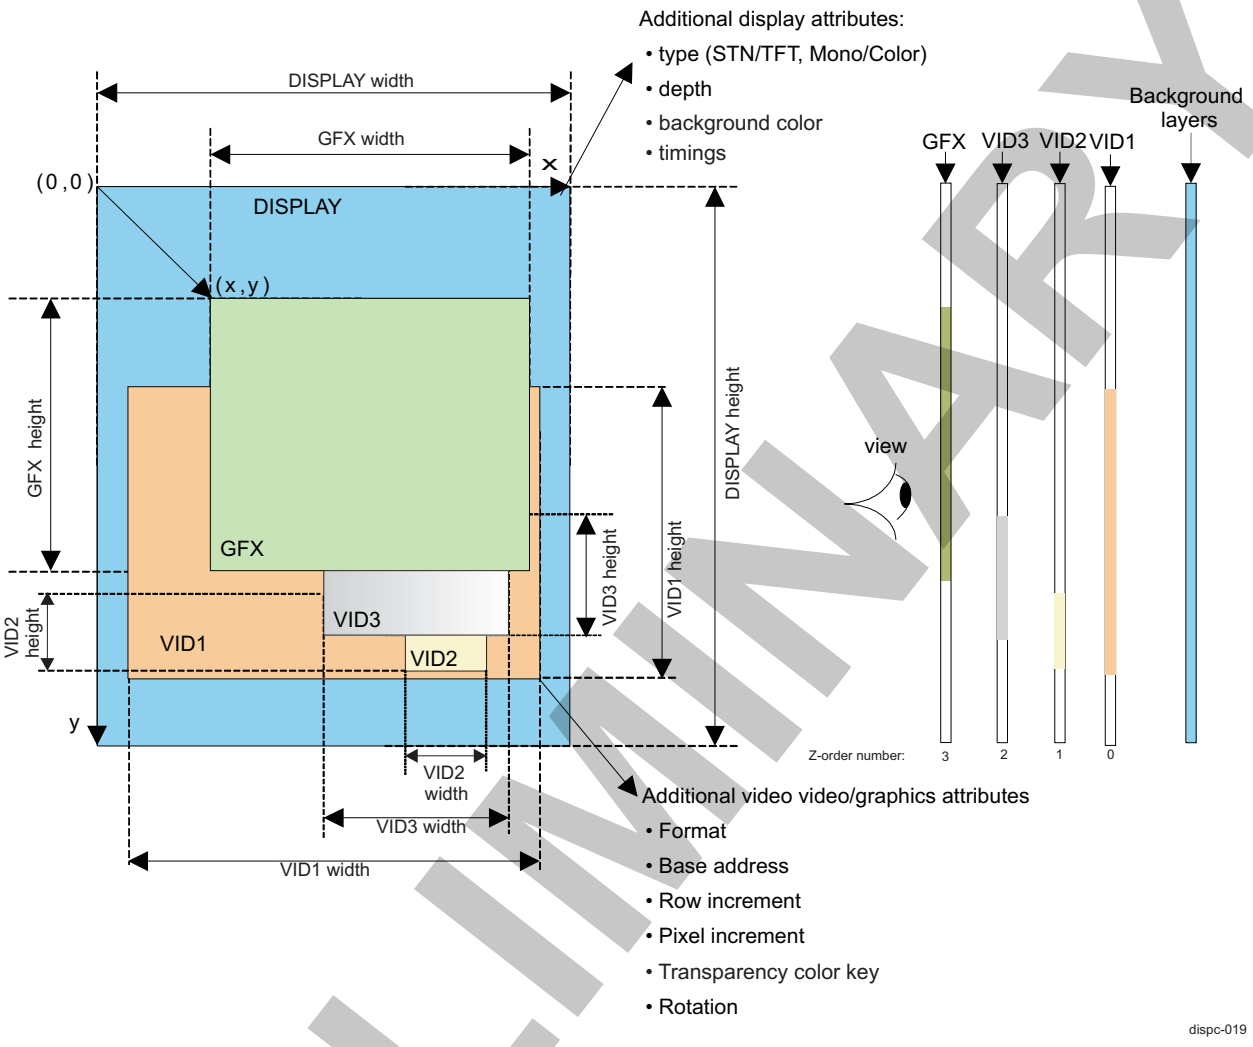
The height and width of each enabled layer (pipeline) must be defined in the SIZEX and SIZEY bit fields DISPC_GFX_SIZE[27:16][11:0]/ DISPC_VIDp_SIZE[27:16][11:0], and its x and y positions defined in the POSX and POSY bit fields DISPC_GFX_POSITION[26:16][10:0]/DISPC_VIDp_POSITION[26:16][10:0]. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears. The solid background color is set in the DISPC_DEFAULT_COLORo[23:0] DEFAULTCOLOR bit field. Figure 10-68 is an example of priority rule.

The Z-order reordering block must always map the pipelines to the blender logic in the same order—from background to foreground.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-68. DISPC Example of Priority Rule: From Lower to Higher VID1, VID2, VID3, GFX



The DISPC is capable of outputting simultaniously two graphic/video windows in frame packing mode. Framepacking mode is enabled from DISPC_GFX_ATTRIBUTES[10] FRAMEPACKINGMODE / DISPC_VIDp_ATTRIBUTES[8] FRAMEPACKINGMODE. The position of the second graphic/video windows is defined in DISPC_GFX_POSITION2 / DISPC_VIDp_POSITION2 registers. The size is again defined in SIZEX and SIZEY bit fields of DISPC_GFX_SIZE[27:16][11:0]/ DISPC_VIDp_SIZE[27:16][11:0] registers.

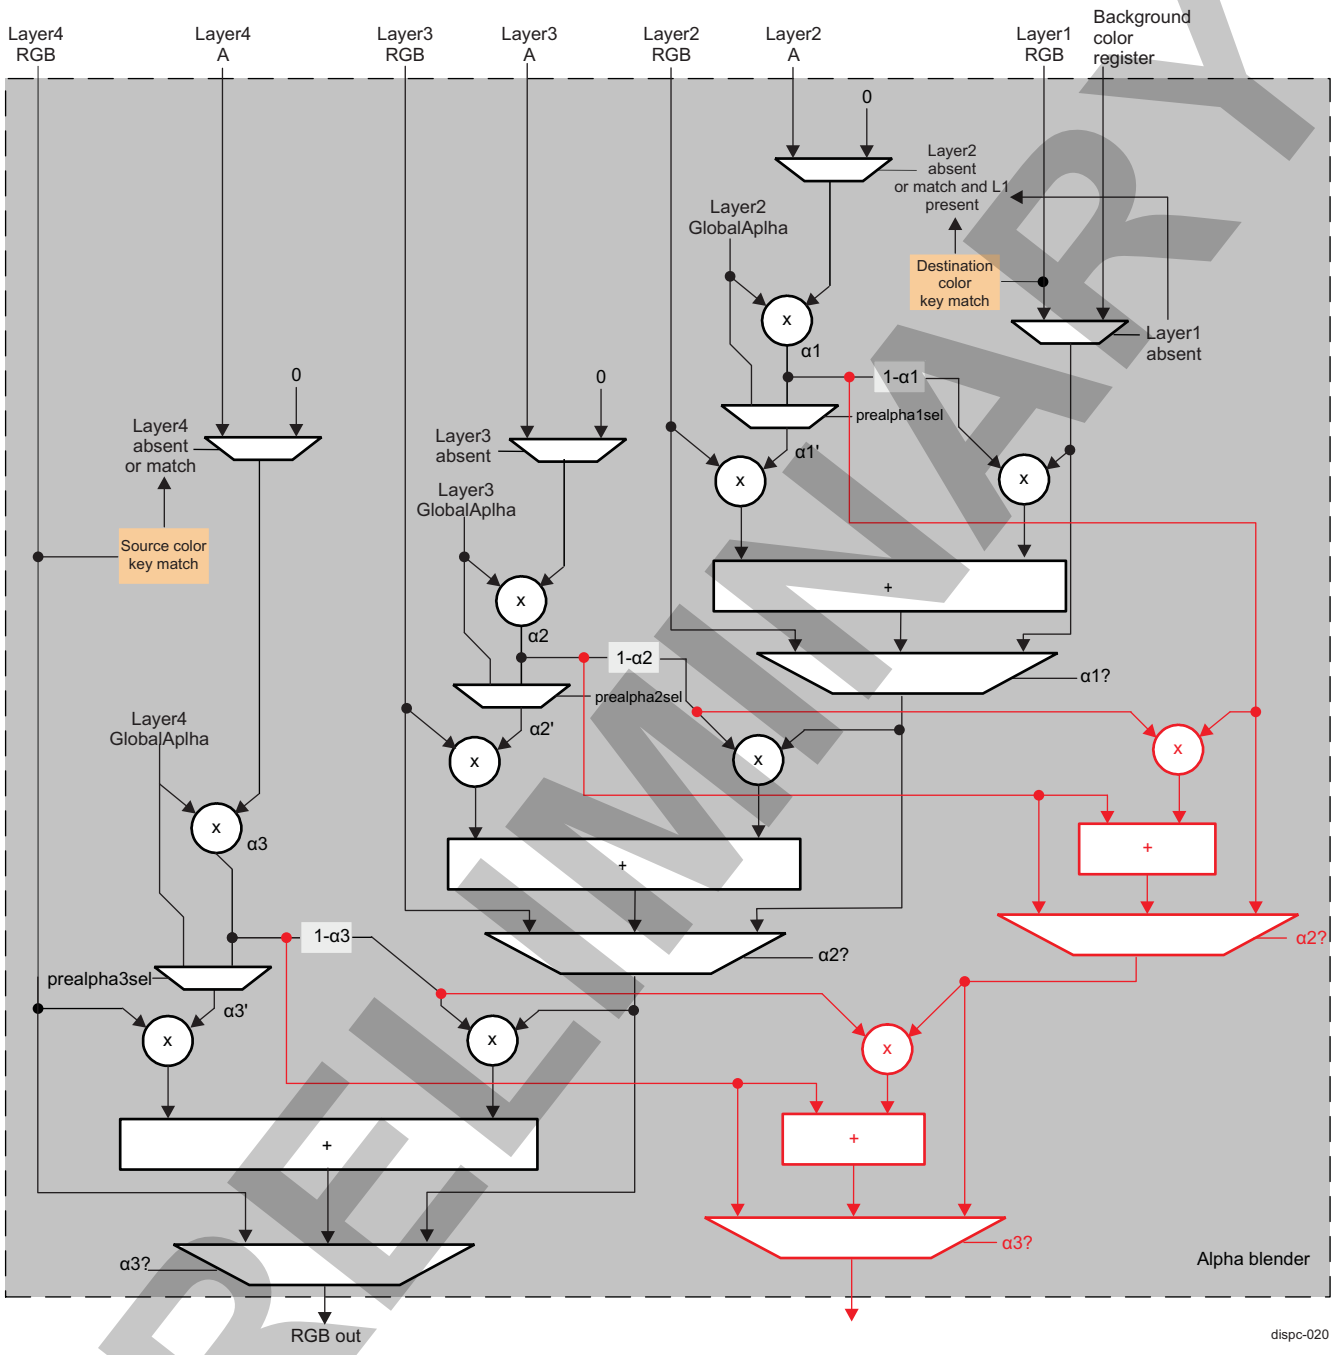
10.2.4.12.1.2 DISPC Alpha Blender

Figure 10-69 shows the alpha blending processing in detail.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-69. DISPC Alpha Blending Architecture With Premultiplied Alpha Support



CAUTION

The Z order of the Source Transparency Layer must have the value 3 (0x3: Z-order 3: layer above all the other layers).

NOTE: 1-alpha operator corresponds to the basic 1s-complement operation.

The alpha blending value is defined by:

- The component value A when using an ARGB or RGBA pixel format.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

  - For ARGB-1555, the alpha blending is defined using a 1-bit value. It is converted into an 8-bit value by duplicating the 1-bit value (see Table 10-50).
  - For ARGB-4444, the alpha blending is defined using a 4-bit value. It is converted into an 8-bit value by duplicating the 4-bit value (see Table 10-50).
  - If the pixel format contains no alpha blending value, the pixel alpha value is considered to be 0xFF and if alpha is equal to 0xFF, there is no multiplication.
  - For BITMAP or YUV formats, there is no alpha blending factor associated with each pixel value. Only the global alpha blending factor associated with the window displaying the BITMAP or YUV format is used.
- The global alpha blending value set in the individual bit fields of the DISPC_GLOBAL_ALPHA register for LCD:
  - VID3GLOBALALPHA
  - VID2GLOBALALPHA
  - VID1GLOBALALPHA
  - GFXGLOBALALPHA
- A total alpha blending value can be used when a combination of the pixel alpha blending value A and a global alpha blending is present. The resulting alpha value is determined as: Alpha = (Pixel Alpha × Global Alpha) / 256.

Table 10-50 lists the percentage of alpha blending in the function of the alpha blending value on 8 bits.

Table 10-50. DISPC Alpha Blending – ARGB

Alpha Blending 1-Bit Value	Alpha Blending 4-Bit Value	Alpha Blending 8-Bit Value (Converted Value or Resulting Alpha)	Percent Blending
0x0	0x0	0x00	100 (transparent)
N/A	0x1	0x11	93.33
N/A	0x2	0x22	86.6
N/A	...	...	...
N/A	0xE	0xEE	6.6
0x1	0xF	0xFF	0 (opaque)

Premultiplied Alpha

The image ARGB may have its RGB component already premultiplied with the alpha (ARGB) where:

- R = A*R
- G = A*G
- B = A*B

In that case, the processing is as follows:

- Color component of premultiplied layers are multiplied with the Global Alpha, if Global Alpha is not equal to 0.
- Color component of the composed underlying layers are multiplied with (1-A) × Global Alpha.

The additional premultiplied alpha option is associated with the pipelines GFX, VID1, VID2, and VID3. The option is accessible through the [28] PREMULTIPLYALPHA bit for the respective pipeline register:

- DISPC_GFX_ATTRIBUTES
- DISPC_VID1_ATTRIBUTES
- DISPC_VID2_ATTRIBUTES
- DISPC_VID3_ATTRIBUTES

The following settings are available:

- PREMULTIPLYALPHA bit = 0: Source is not premultiplied with alpha. Full blending is done in the DISPC.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

- PREMULTIPLYALPHA bit = 1: Source is premultiplied with alpha. Partial blending is done.

NOTE: The *prealphasel* controls in Figure 10-69, correspond to the PREMULTIPLYALPHA of the pipelines mapped on the respective layers.

The logic marked in red in Figure 10-69 corresponds to the alpha value, computed when the write-back channel copies back to memory the premultiplied color component: A (destination) = A (source) + (1-A (source) × A (destination))

When the DISPC_WB_ATTRIBUTES[7] ALPHAENABLE bit is cleared, or when the overlay channel is not selected for WB, the computation of the A(destination) is disabled. The default value for DISPC_WB_ATTRIBUTES[7] ALPHAENABLE bit is 0x0. When the WB is configured to copy back one of the output channels (output of overlay), the following configurations are available:

- The ALPHAENABLE bit is set to 0x1: The WB pipe copies back to memory the premultiplied alpha calculated through the overlay.
- The ALPHAENABLE bit is set to 0x0: The alpha value is not written back.

NOTE: The DISPC_WB_ATTRIBUTES[7] ALPHAENABLE bit is effective only when one of the output channels is written back, otherwise it is ignored.

10.2.4.12.1.3 DISPC Transparency Color Keys

The two transparency color keys are the source transparency color key and the destination transparency color key. The transparency color key can be used only with BITMAP formats (1-, 2-, 4-, and 8-bpp) and RGB formats (ARGB, RGB, RGBA, xRGB, and RGBx). in this case the A information is ignored for the comparison between the pixel value and the color key value. It is possible to use YUV formats with some care because the comparison is between the input pixel value of the overlay manager from pipeline (GFX or one of the VID pipelines depending on the Z-order) and the color key value. The YUV data is converted to RGB format. If the original format is YUV, the user must consider the color space conversion processing to define the RGB color key value used for the comparison.

The transparency color key is enabled by setting the following bits to 0x1:

- DISPC_CONFIG1[10] TCKLCDENABLE (for LCD1)
- DISPC_CONFIG2[10] TCKLCDENABLE (for LCD2)
- DISPC_CONFIG3[10] TCKLCDENABLE (for LCD3)
- DISPC_CONFIG1[12] TCKTVENABLE (for TV)

The transparency color key is determined in the following bit fields.

- DISPC_TRANS_COLOR0[23:0] TRANSCOLORKEY (for LCD1)
- DISPC_TRANS_COLOR2[23:0] TRANSCOLORKEY (for LCD2)
- DISPC_TRANS_COLOR3[23:0] TRANSCOLORKEY (for LCD3)
- DISPC_TRANS_COLOR1[23:0] TRANSCOLORKEY (for TV)

NOTE:

- The video source transparency color key and graphics destination transparency color key cannot be active at the same time.
- For CLUT bitmaps, the palette index is compared to the transparency color key and not to the palette value pointed out by the palette index.

- Video source transparency color key

  The value of the video source transparency color key defines the encoded pixel data considered as a transparent pixel. The encoded pixel values with the source color key value are not visible, and the encoded pixel values of the under layers or solid background color are visible (the pixel alpha blending value of layer 4 is forced to 0x00, fully transparent).

  The scaler can be enabled as a preprocessor in the VID pipeline, but it is necessary to consider the

Copyright © 2013, Texas Instruments Incorporated
PRELIMINARY

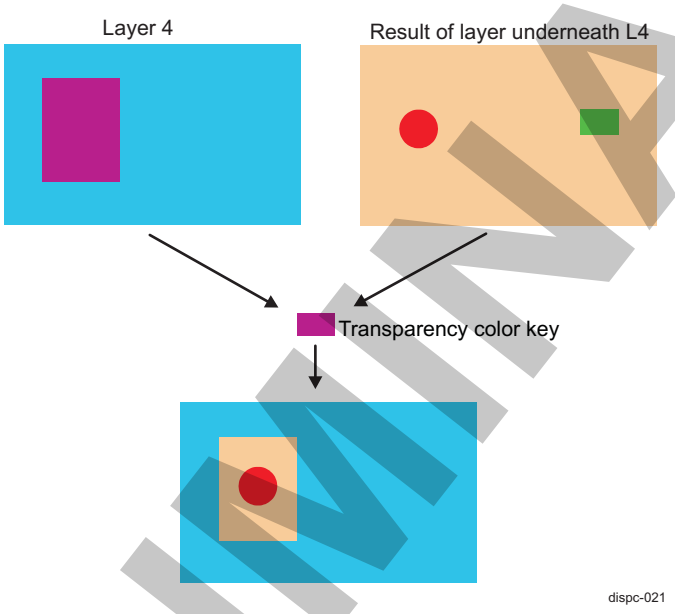
pixel scaling preprocessing in order to define the color key value to be used after the rescaling for the comparison between the input pixel value to the overlay manager and the color key value.

The source transparency color key mode is selected by setting the following bits to 0x1:

– DISPC_CONFIG1[11] TCKLCDSELECTION (for LCD1)
– DISPC_CONFIG2[11] TCKLCDSELECTION (for LCD2)
– DISPC_CONFIG3[11] TCKLCDSELECTION (for LCD3)
– DISPC_CONFIG1[13] TCKTVENABLE (for TV)

Figure 10-70 shows an example of source color key. The pixels with the transparency color key are not displayed; instead, pixels of the resulting layer underneath are shown.

Figure 10-70. DISPC Source Transparency Color Key Example



- Graphics destination transparency color key value

  The graphics destination transparency color key value defines the encoded pixels in layer 1, which are not displayed. Other layer 1 pixels (nonequal to destination transparency color key) are displayed over layer 2. The encoded pixel values with the destination color key value are pixels not visible on the screen because pixels at the same position in layer 2 are visible; otherwise, encoded pixels are visible above layer 2 . The destination transparency color key applies only if layer 1 overlaps layer 2 (see the Z-order section for details on layer position depending on the Z-order parameter in Section 10.2.4.12.1.1, *Priority Rule*); otherwise, the destination transparency color key is ignored.

  The scaler can be enabled as a preprocessor in the VID pipeline. It is necessary, however, to consider the pixel scaling preprocessing in order to define the color key value to be used after rescaling for the comparison between the input pixel value to the overlay manager and the color key value.

  The destination transparency color key mode is selected by setting the following bits to 0x0:

  – DISPC_CONFIG1[11] TCKLCDSELECTION (for LCD1)
  – DISPC_CONFIG2[11] TCKLCDSELECTION (for LCD2)
  – DISPC_CONFIG3[11] TCKLCDSELECTION (for LCD3)
  – DISPC_CONFIG1[13] TCKTVSELECTION (for TV)

  Figure 10-71 shows an example of the destination color key. The pixels, equal to the transparency color key, are not displayed and are replaced by layer 2 pixels. All other layer 1 pixels, different from the transparency color key, are displayed over layer 2.

PRELIMINARY

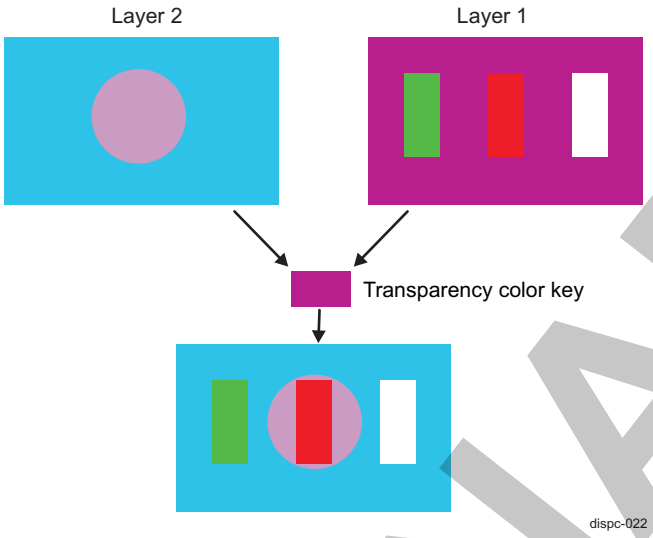
Figure 10-71. DISPC Destination Transparency Color Key Example



10.2.4.12.1.4 DISPC Overlay Optimization

The overlay optimization consists in fetching only the required pixels (that is, pixels that contribute to the final picture to be displayed [LCD1, LCD2, LCD3, or TV]). The decision to fetch the pixel from memory is based on the information available in the registers and on the following rules:

- The layer is enabled.
- The global alpha blending factor for the layer is different than 0x00.
- The current layer is behind an nonopaque layer (global alpha blending factor is different than 0xFF for the layer in the preceding).

The result of the overlay optimization is a reduction of the bandwidth by fetching only the mandatory pixels. The overlay mechanism is independent for each overlay: LCD1, LCD2, LCD3, and TV. Because each layer (GFX, VID1, VID2, and VID3) can be associated to only one overlay at a time, it is possible to optimize the fetch of the pixels for each layer based on the overlay information. The overlay optimization must be run on the DMA engine time window and not on the display time window. The pixels are fetched by the DMA engine before the display processing.

The overlay optimization is enabled by setting the following bits to 0x1:

- DISPC_CONTROL1[12] OVERLAYOPTIMIZATION (for LCD1)
- DISPC_CONTROL2[12] OVERLAYOPTIMIZATION (for LCD2)
- DISPC_CONTROL3[12] OVERLAYOPTIMIZATION (for LCD3)
- DISPC_CONTROL2[13] TVOVERLAYOPTIMIZATION (for TV)

NOTE:

- The overlay optimization is not functional when a layer is using BITMAP1, BITMAP2, BITMAP3, or BITMAP4 pixel formats.
- The pixel alpha blending factor in case of ARGB and RGBA formats cannot be used to take advantage of the pixel fully transparent (alpha blending factor equals 0x00).
- By default, the overlay optimization is disabled (OVERLAYOPTIMIZATION bits = 0x0 for all DISPC outputs), and all the data for all the enabled pipelines are fetched from memory regardless of the overlay or alpha blending configuration.

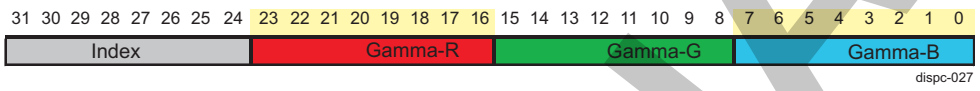
10.2.4.12.2 DISPC Gamma Correction Unit

In gamma curve mode, the selected encoded pixel values based on the color keys by the overlay manager from the video or graphics paths are sent to the gamma curve table. Each component of encoded pixel value is used as a pointer to index 1 out of 256 24-bit gamma curve entries in the table. Each 8-bit component is replaced with the 8-bit table value corresponding to R, G, or B component. The table is loaded by software. It is possible to load only part of the table. For each access to the table, the 24-bit value is associated with index in the table by concatenating the 24-bit value (LSB of 32-bit access) and the 8-bit index value (MSB of the 32-bit access). Figure 10-72 describes the format of one of the gamma curve values in the memory.

NOTE: If the CLUT is used in the GFX pipeline for palette, the gamma correction unit is not available on the primary LCD.

Figure 10-72. DISPC Data Memory Organization for Gamma Mode in LCD Output



10.2.4.12.3 DISPC Color Phase Rotation Unit

The CPR unit can be used to correct the LCD output colorimetry in case of nonpure white backlight.

The CPR is enabled by setting the DISPC_CONFIGo[15] CPR bit to 0x1. The coefficients are programmed in the following registers:

- Red 10-bit signed coefficients in DISPC_CPRo_COEF_R
- Green 10-bit signed coefficients in DISPC_CPRo_COEF_G
- Blue 10-bit signed coefficients in DISPC_CPRo_COEF_B

The CPR can be selected for active matrix panel. The logic is integrated after the LCD overlay manager or the palette while using the gamma correction and before the spatial/temporal dithering. The CPR can be selected to correct the nonpure white backlight of the LCD module by using a programmable matrix to convert the 24-bit RGB pixel value into a new 24-bit RGB pixel value. The matrix is programmed through a set of nine 10-bit signed coefficients. The output of the calculation is clipped to [0:255]. The CPR is processed by the equation shown in Figure 10-73. Table 10-51 lists all coefficients with their respective bit field registers for settings.

Figure 10-73. DISPC CPR Matrix

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \begin{bmatrix} Rr & Rg & Rb \\ Gr & Gg & Gb \\ Br & Bg & Bb \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

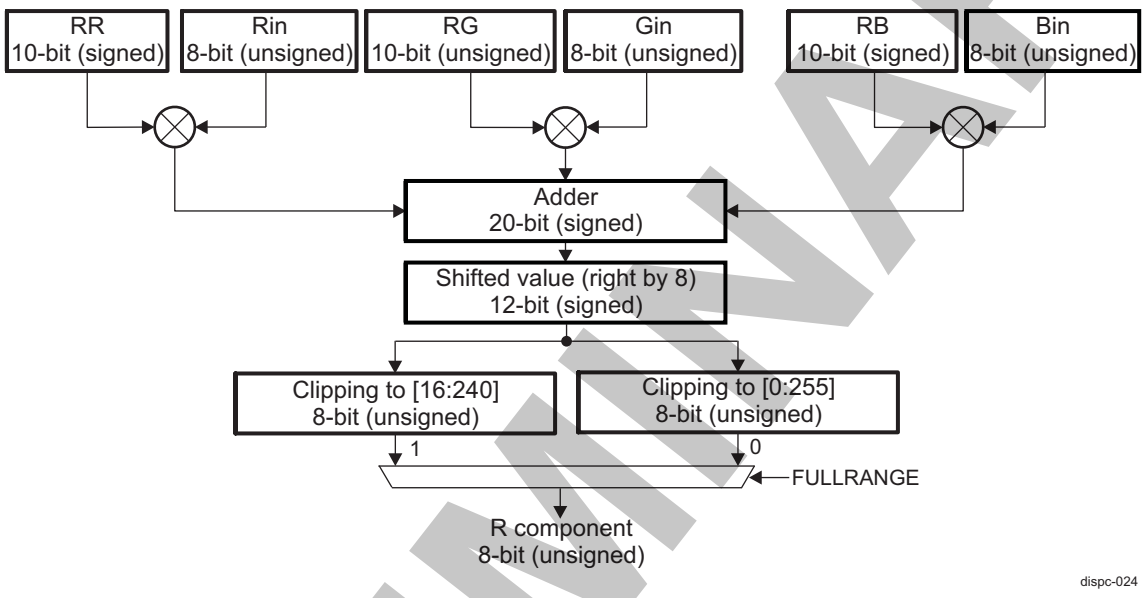
Figure 10-74 shows the CPR macro-architecture.

Figure 10-74. DISPC CPR Macro-Architecture



10.2.4.12.4 DISPC Active Matrix

Depending on the color depth, the active matrix output:

- 24 bpp supports 16,777,216 colors.
- 18 bpp supports 262,144 colors.
- 16 bpp supports 65,536 colors.
- 12 bpp supports 4096 colors.

When in active matrix path configuration, after setting the DISPC_CONTROLo[3] STNTFT bit to 0x1, two submodules must be configured:

- Spatial/temporal dithering
- Multiple cycle output format (TDM)

10.2.4.12.4.1 DISPC Spatial/Temporal Dithering

When the active matrix path is used, the spatial/temporal dithering logic can be selected to enhance the quality of the active matrix outputs. The encoded pixel values are used by spatial/temporal dithering logic to display the data in a lower color depth on the LCD panel. The dithering logic is integrated after the CPR and before the TDM. The spatial/temporal dithering algorithm is based on the (x,y) pixel position and frame rate control. The dithering logic can process the pixels over one frame, two frames, or four frames. The number of frames is selected by setting the DISPC_CONTROLo[31:30] SPATIALTEMPORALDITHERINGFRAMES bit field. In the case of a single frame, only spatial processing is applied, and in multiple frames, spatial and temporal processing are applied to the pixels. The spatial/temporal dithering logic is enabled by setting the DISPC_CONTROLo[7] STDITHERENABLE bit to 0x1.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE:

- If the interface data bus is smaller than the pixel format size and spatial/temporal dithering is not enabled, the MSBs of the pixel color components are output on the interface data bus.
- If the interface data bus is larger than the pixel format size, by programming the pixel components replication active/inactive, the MSB is replicated to the LSB of the interface data bus or the LSB is filled with 0s.

10.2.4.12.4.2 DISPC Multiple Cycle Output Format (TDM)

The pixels, after the active matrix display processing, are formatted on one or multiple cycles (a maximum of three cycles). The number of bits for each cycle is set in the DISPC_DATAo_CYCLE1 register for the first cycle, the DISPC_DATAo_CYCLE2 register for the second cycle, and the DISPC_DATAo_CYCLE3 register for the third cycle. The interface data bus width can be 8, 9, 12, or 16 bits. The configuration of the data bus is done in the DIPSC_CONTROLo[9:8] TFTDATALINES bit field.

When the TDM is disabled, the DISPC outputs the pixels using the conventional formats: active matrix display monochrome/color.

Figure 10-75 through Figure 10-78 show various examples of TDM settings in the function of pixel data formats and the interface data bus width.

10.2.4.12.5 DISPC Synchronized Buffer Update

A synchronization mismatch between the frame buffer and the display refreshes, named tearing effect, can lead to images that appear to be stretched on the screen. To avoid it, a synchronization mechanism is used between the DISPC and the process that updates the buffer. An interrupt is generated when the display reaches a predefined line number. The PROGRAMMEDLINENUMBER_IRQ interrupt (DISPC_IRQSTATUS and DISPC_IRQENABLE) is a level signal and stays active during the programmed line of the display.

10.2.4.12.6 DISPC Timing Generator and Panel Settings

The size of and panel is defined by:

- Number of lines, DISPC_SIZE_LCDo[27:16] LPP bit field, with a value from 1 to 4096
- Number of pixels per line, DISPC_SIZE_LCDo[11:0]PPL bit field, with a value from 1 to 4096

Standard HSYNC/VSYNC timing generation are programmable for each LCD outputs independently:

- Horizontal front porch is set in the DISPC_TIMING_Ho[19:8] HFP bit field.
- Horizontal back porch is set in the DISPC_TIMING_Ho[31:20] HBP bit field.
- Horizontal synchronization pulse width is set in the DISPC_TIMING_Ho[7:0] HSW bit field.
- Vertical front porch is set in the DISPC_TIMING_Vo[19:8] VFP bit field.
- Vertical back porch is set in the DISPC_TIMING_Vo[31:20] VBP bit field.
- Vertical synchronization pulse width is set in the DISPC_TIMING_Vo[7:0] VSW bit field.

Horizontal/vertical synchronization and ACBIAS signals polarity are programmable by setting the DISPC_POL_FREQo[12] IVS, DISPC_POL_FREQo[13] IHS, and DISPC_POL_FREQo[15] IEO bits. These signals can be gated by setting the DISPC_CONFIGo[7] VSYNCGATED and DISPC_CONFIGo[6] HSYNCGATED bits.

The latch of data can be driven on the rising or falling edge of the pixel clock by setting the DISPC_POL_FREQo[14] IPC bit. The drive of the SYNC and VSYNC signals in the function of the pixel clock is done by setting the DISPC_POL_FREQo[16] RF bit.

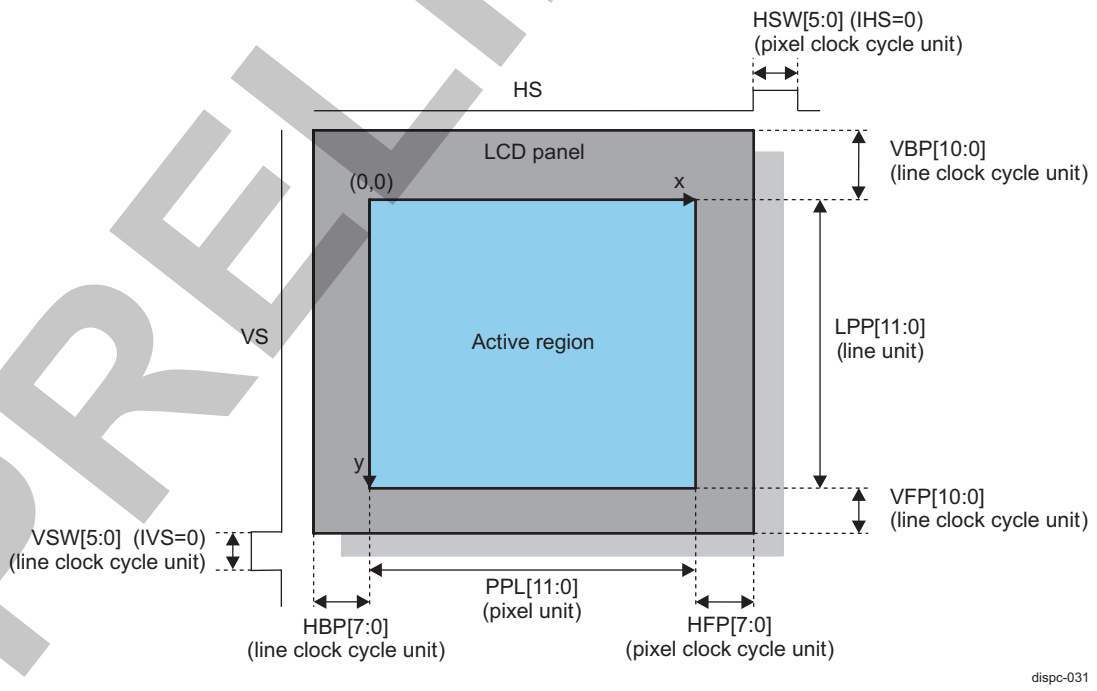
Table 10-52 describes the programming rules for LCD timing.

Table 10-52. DISPC Programming Rules

	No Downsampling	Downsampling H or V	Downsampling H + V
(HBP + HSW + HFP) × PCD	>8	>10	>20

Figure 10-79 shows the timing values description in the case of an active matrix display.

Figure 10-79. DISPC Timing Values (Active Matrix Display)



PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The 8-bit pixel clock divider (the DISPC_DIVISORo[7:0] PCD bit field) selects the pixel clock frequency. This bit field generates a range of pixel clock frequencies from LC/2 to LC/256, where LC is the logic clock from the divided functional clock of the DISPC by the DISPC_DIVISOR[23:16] LCD bit field.

The pixel clock is defined by the following equation:

Pixel Clock = (FunctionalClock/LCD[7:0])/PCD[7:0]

The pixel clock can be gated by setting the DISPC_CONFIGo[5] PIXELCLOCKGATED bit to 0x1.

The LCD output can be configured in progressive output or interlace output. The selection is done by writing into the DISPC_CONFIGo[22] OUTPUTMODEENABLE bit. The reset value is 0x0, which means progressive mode. When progressive mode is selected, the FID signal associated to the LCD output is driven low (INACTIVE state). The selection can be changed only if the corresponding LCD output is disabled. The configuration is independent for each LCD output.

When in interlaced mode, the DISPC_CONFIGo[23] FIDFIRST bit indicates which field is output first:

- 0x0: Even field first (FID = 0)
- 0x1: Odd field first (FID = 1)

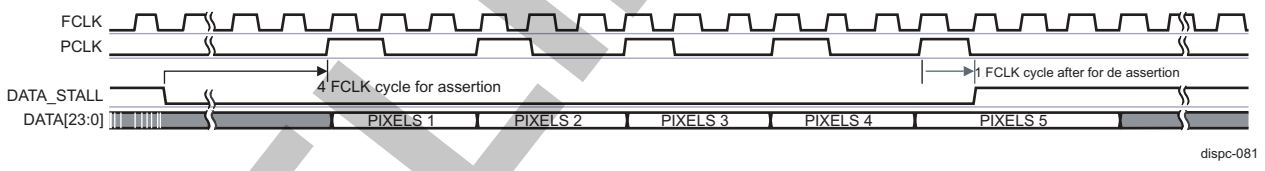
10.2.4.12.7 DISPC Stall Mode

Stall mode is used to indicate when the DISPC must stop sending data on the corresponding LCD output interface to avoid an overflow on the interface level. Stall mode is available when the RFBI and DSI interfaces are used. The Interface asserts the stall signal to stop data output by the DISPC. It is deasserted by the interface to indicate when new data must be output by the DISPC. Figure 10-80 shows the RFBI data stall mode activated.

Stall mode is selected by setting the DISPC_CONTROLo[11] STALLMODE bit.

NOTE: The DISPC_CONTROLo[5] GOLCD bit must not be set, but the DISPC configuration (DMA engine, pipelines associated with the LCD output) must be set before enabling the LCD output by setting the DISPC_CONTROLo[1] LCDENABLE bit.

Figure 10-80. DISPC RFBI Data Stall Signal Diagram

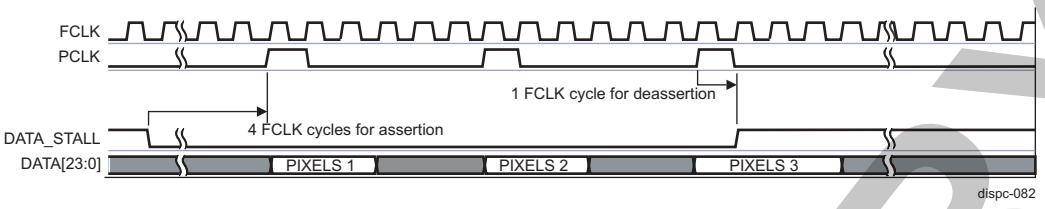


To avoid an underflow of the DMA buffer, the DMA buffer handshake must be enabled by setting the DISPC_CONFIGo[16] BUFFERHANDCHECK bit. The fullness of the buffers associated to the pipelines used for the LCD output is checked before providing data to the pipeline when the STALL signal is inactive. It prevents emptying the DMA buffer when the RFBI or DSI module requests data and there is not enough data in the DMA buffer of the DISPC. This feature must be enabled only when stall mode is used (the STALLMODE bit set to 0x1). When the DMA buffer handshake is activated, the pixel transfer to the RFBI or DSI module, outside a STALL period, can be stopped and restarted when there are enough data in the DMA buffer. The DMA buffer handshake ensures that the underflow does not occur for the pipelines associated with the LCD output when RFBI/DSI interfaces are used. The rate of the data transfer to the RFBI or DSI is, then, fully dependent on the state of the DMA buffer. Figure 10-81 shows the RFBI data stall with FIFO handcheck mode activated.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-81. DISPC RFBI Data Stall Signal Diagram With Handcheck



Stall mode is independently used when the RFBI or DSI protocol engines are connected to the LCD outputs and receive the pixels to reformat the data.

The STALL signals from the RFBI and DSI interfaces are merged into a single signal in the display subsystem. Only one signal for each LCD output is connected to the DISPC. Figure 10-82 shows the STALL signal implementation.

Two STALL signals are generated by the RFBI. The RFBI module asserts the STALL signal when no more data must be output by the DISPC. STALL is deasserted to indicate when new data must be output by the DISPC.

Two STALL signals are generated by the DSI1_A protocol engine. It is used by the DSI1_A protocol engine when data are provided from the DISPC to the DSI1_A protocol engine using the two video ports in command mode only. If one of the two video ports is in video mode, the STALL signal associated with the video port from the DSI1_A protocol engine is not used (it must be in INACTIVE state from the DSI1 protocol engine).

Two STALL signals are generated by the DSI1_C protocol engine. It is used by the DSI1_C protocol engine when data are provided from the DISPC to the DSI1_C protocol engine using the two video ports in command mode only. If one of the two video ports is in video mode, the STALL signal associated with the video port from the DSI1_C protocol engine is not used (it must be in INACTIVE state from the DSI1_C protocol engine).

10.2.4.13 DISPC TV Output

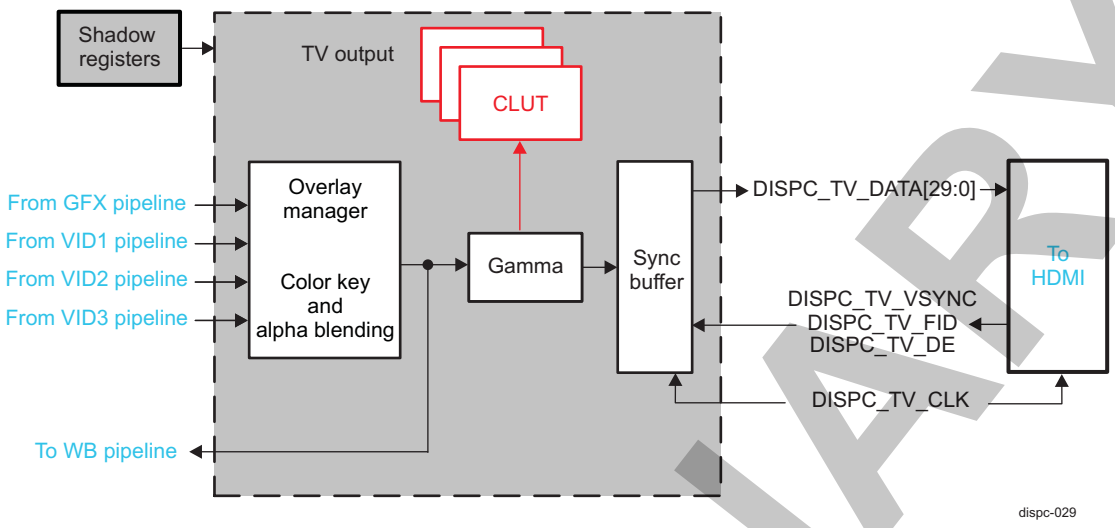
The TV output paths consist of several processing blocks (see Figure 10-83):

- Overlay manager
- Gamma correction unit
- Synchronization buffer

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-83. DISPC TV Output Architecture



The TV output is connected to the HDMI. In analog output or HDMI, the DISPC TV output receives an external clock, DISPC_TV_CLK, and based on the VSYNC generated by the HDMI, hold time, vertical offset, and horizontal offset, outputs the pixels synchronously. The size of the field/frame to output defines the number of pixels to output on each line and the number of lines for each field/frame.

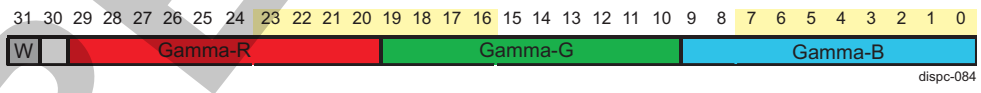
10.2.4.13.1 DISPC Overlay Manager

The overlay mechanism is identical in LCD1, LCD2, and LCD3 (see Section 10.2.4.12.1, *Overlay Manager*).

10.2.4.13.2 DISPC Gamma Correction Unit

The gamma correction unit works as described in Section 10.2.4.12.2, *Gamma Correction Unit*. The only difference is in the input pixel format RGB30. Each component of encoded pixel value is used as a pointer to index 1 out of 1024 30-bit gamma curve entries in the table. Each 10-bit component is replaced with the 10-bit table value corresponding to R, G, or B component. The table is loaded by software, through the DISPC_GAMMA_TABLE2 register. It is possible to load only part of the table. For each write access to the table, the 30-bit gamma value is associated with bit [31] INDEX to indicate that a new table is defined. Setting bit [31] INDEX to 0x1 for the first time, resets the internal index counter. All the following accesses are considered to be for incremented index addressing in the table (bit [31] INDEX is set to 0 for each subsequent access). Figure 10-84 shows the format of one of the gamma curve values in the memory.

Figure 10-84. DISPC Data Memory Organization for Gamma Mode in TV Output



10.2.4.13.3 DISPC Synchronized Buffer Update

The synchronized buffer update is identical in LCD1, LCD2, and LCD3 (see Section 10.2.4.12.5, *Synchronized Buffer Update*).

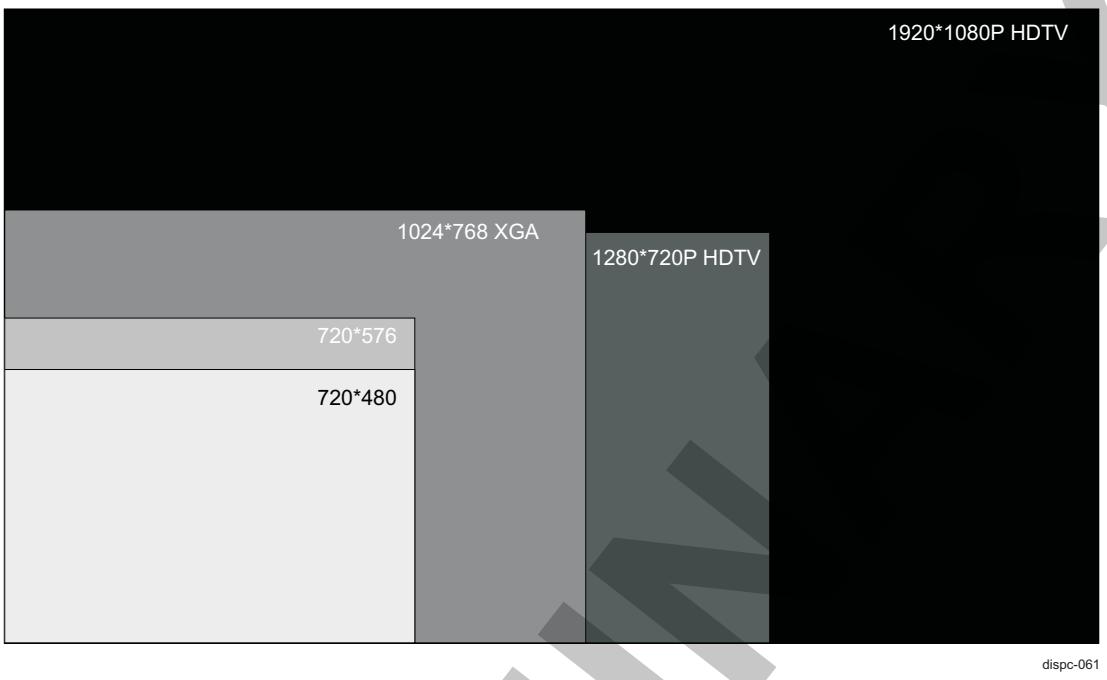
10.2.4.13.4 DISPC Timing and TV Format Settings

Figure 10-85 shows the TV formats supported.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-85. DISPC Example Timing TV Formats



The size of a TV output format is defined by:

- Number of lines, DISPC_SIZE_TV[27:16] LPP bit field, with a value from 1 to 4096
- Number of pixels per line, DISPC_SIZE_TV[11:0] PPL bit field, with a value from 1 to 4096
- Delta size between odd/even field, DISPC_SIZE_TV[15:14] DELTA_LPP bit field. This bit field controls only the output channel and not the size of the data field fetched from the frame buffer in memory.

The hold time of the pixels on the data bus is determined in clock cycles by the DISPC_CONTROL1[19:17] HT bit field. The default value at reset time is 0x0 (one cycle).

- When connected to the HDMI encoder, Table 10-53 indicates the DISPC_SIZE_TV (PPL and LPP) value for each HD standard.

Table 10-53. DISPC PPL and LLP Value for HD Standard

Standards		Active Pixels/Line	Active Lines	Digital Clock	DISPC_SIZE_TV
HDTV	720p	1280	720	74.25/74.125 MHz (60/59.99..frames/s)	0x02CF 04FF
	1080i	1920	540	74.25/74.125 MHz (60/59.99..frames/s)	0x021B 07FF
	1080p	1920	1080	148.5/148.25 MHz (60/59.99..frames/s)	0x0437 07FF
	720p 3D (frame packing)	1280	1470	148.5/148.35/148.5 MHz (60/59.94/50 frames/s)	0x05BD 04FF
	1080p 3D (frame packing)	1920	2205	148.5/148.35 MHz (24/23.98 frames/s)	0x089C 07FF
	1080p 3D (side-by-side half)	1920	1080	148.5 MHz (60 frames/s)	0x0437 07FF

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: When configuring the DISPC for outputting any supported 3D frame-packing format, the following generic details must be considered:

- As defined by the *HDMI v1.4 Specification*, Section 8.2.3.2, 3D frame-packing is a video format structure composed of two stereoscopic pictures: left and right.
- The stereoscopic pictures can be processed through the three video pipelines (VID1, VID2, or VID3). For more information about the configuration of video pipelines, see Section 10.2.4.10, *Video Pipelines*.
- The 3D frame is generated by setting the TV overlay manager to combine the outputs of the selected video pipelines that hold the pictures. One video pipeline (VID1 or VID3) must carry the top field of the 3D frame (left stereoscopic picture), and the other video (VID2) pipeline must always carry the bottom field of the frame (right stereoscopic picture). The top and bottom fields are separated by an active space area. For more information, see the *HDMI v1.4 Specification*, Section 8.2.3.2.
- The pipeline carrying each field (top and bottom) of the 3D frame must have its height and width parameters defined in the [27:16] SIZEY and [11:0] SIZEX bit fields of the DISPC_VIDp_SIZE register, and its Y and X positions defined in the [26:16] POSY and [10:0] POSX bit fields of the DISPC_VIDp_POSITION register. The active space area of the 3D frame can be encoded by setting the solid background color for the TV output (the DISPC_DEFAULT_COLOR1[23:0] DEFAULTCOLOR bit field). For more information about the overlay mechanism, see Section 10.2.4.13.1, *DISPC Overlay Manager*.

10.2.4.14 DISPC Extended 3D Support

The DISPC supports several formats to support 3D displays. The following three sections provide further details.

10.2.4.14.1 DISPC Extended 3D Support - Line Alternative Format

Line alternative format is defined by the HDMI Specification 1.4a. In general the the functionality is:

- Lines from the left and the right frames are interleaved alternatively on the screen to produce a 3D image.
- Required also to support interleaving column-wise to support all possible screen orientations.

The functionality is done in the overlay manager:

- The layers are grouped into two categories based on the z-order: Odd z-order may blend together and will interleave with even z-order pipes, which may blend together.
- Two types of interleaves are possible, line-based interleaving and pixel-based interleaving to support landscape and portrait screen orientations.

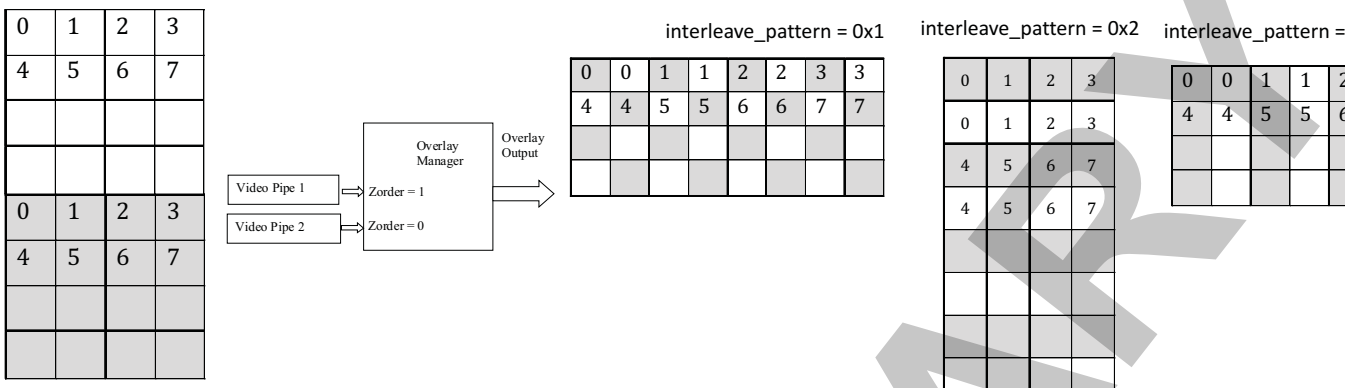
The configuration is done from the DISPC_CONFIG1[29:28] TVINTERLEAVE for the TV output, DISPC_CONFIG1[27:26] PLCDINTERLEAVE for the primary LCD, DISPC_CONFIG2[27:26] SLCDINTERLEAVE for the secondary LCD, and DISPC_CONFIG3[27:26] TLCDINTERLEAVE for the third LCD. The following values apply for the these bitfields:

- 0x0: If zero then no interleaving happens in the overlay manager.
- 0x1: Checkerboard pattern:
  - All even pixels on even lines have a contribution from even z-order pipes.
  - All odd pixels on even lines have a contribution from odd z-order pipes.
  - All even pixels on odd lines have a contribution from odd z-order pipes.
  - All odd pixels on odd lines have a contribution from even z-order pipes.
- 0x2: All even lines (all pixels) have a contribution from even z-order pipes. All odd lines (all pixels) have a contribution from the odd z-order pipes.
- 0x3: All even pixels (for all lines) have a contribution from even z-order pipes. All odd pixels (for all lines) have a contribution from the odd z-order pipes.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-86. DISPC Illustration of 3D Interleaving

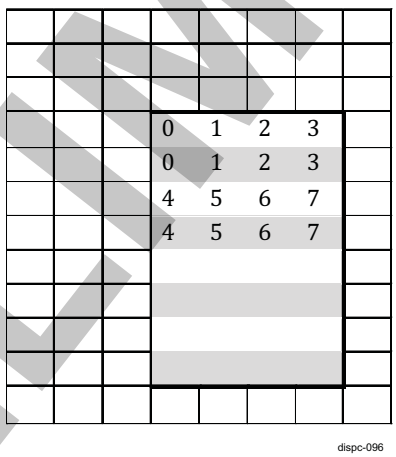


Moreover, from the above figure if interleave_pattern is programmed as 0x2, in this case the entire screen composited by the overlay manager (ppl x lpp) gets sub-divided into odd and even lines. It is possible for a 3D window created using the two pipes to have a non-zero position (i.e. posx and posy not equal to zero).

In such cases depending on the oddness or evenness of the posy setting, the first line in the window maybe from video pipe 1 or video pipe 2.

For instance if the posx =3, posy =3 (set in DISPC_GFX_POSITION, DISPC_VID1_POSITION, DISPC_VID2_POSITION, DISPC_VID3_POSITION registers), then the final composited screen with ppl =8, lpp =12 may look like below:

Figure 10-87. DISPC Illustration of a Non-zero Position of 3D Window



NOTE: In this case the first line comes from the odd-zorder pipe i.e. Video Pipe 1.

The following limitations apply to the 3D Line alternative format:

- Software must ensure that the left/right frames are of same size.
- Software must ensure that in case of line interleaving the sizey is not greater than lpp/2.
- Software must ensure that in case of pixel interleaving the sizex is not greater than ppl/2.
- Software must program PosX and PosY for both left and right frame to be the same.
- Color-keying is not available for 3D formats.
- Since each overlay manager can support 4k x 4k frames, max resolution of each left/right frame will be restricted to 2k x 2k.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

10.2.4.14.2 DISPC Extended 3D Support - Frame Packing Format Format

In this mode the pipe fetches two windows (of SizeX X SizeY) during a complete panel frame (ppl X lpp). The mode is enabled from DISPC_GFX_ATTRIBUTES[10] FRAMEPACKINGMODE and DISPC_VID1_ATTRIBUTES[8], DISPC_VID2_ATTRIBUTES[8], DISPC_VID3_ATTRIBUTES[8] FRAMEPACKINGMODE

The position for the first window is set in DISPC_GFX_POSITION, DISPC_VID1_POSITION, DISPC_VID2_POSITION, DISPC_VID3_POSITION, while the position for the second window is set in DISPC_GFX_POSITION2, DISPC_VID1_POSITION2, DISPC_VID2_POSITION2, DISPC_VID3_POSITION2

When it is detected that a pipe has finished sending the programmed number of lines to the overlay or write-back pipe, a reset is generated for the pipe as well as the DMA channel associated with the pipe. At the same instant, the base address configuration for the DMA channel is changed from the BA0 to the BA1.

Due to the reset the pipe and DMA starts fetching the data from BA1. At the end of the processing of BA1 data, the DMA channel and the pipe become idle and clock gated.

The overlay manager composes the final frame to be sent to the panel and uses the posx, posy coordinates for the first window and posx2, posy2 for the second window.

The following limitations apply to the 3D Frame Packing format:

- Only frame packing for progressive mode is supported. Frame packing of interlaced formats is not supported.
- End-of-window interrupts will be generated twice per outgoing-frame.
- Flip Immediate will not work as expected.
- It is software responsibility to calculate and program the posx2, posy2 as per the active space required by the panel.

10.2.4.14.3 DISPC Extended 3D Support - DLP 3D Format

The DLP 3D format sub-samples the left and right frames across the diagonal before interleaving the frames in a checker-board fashion.

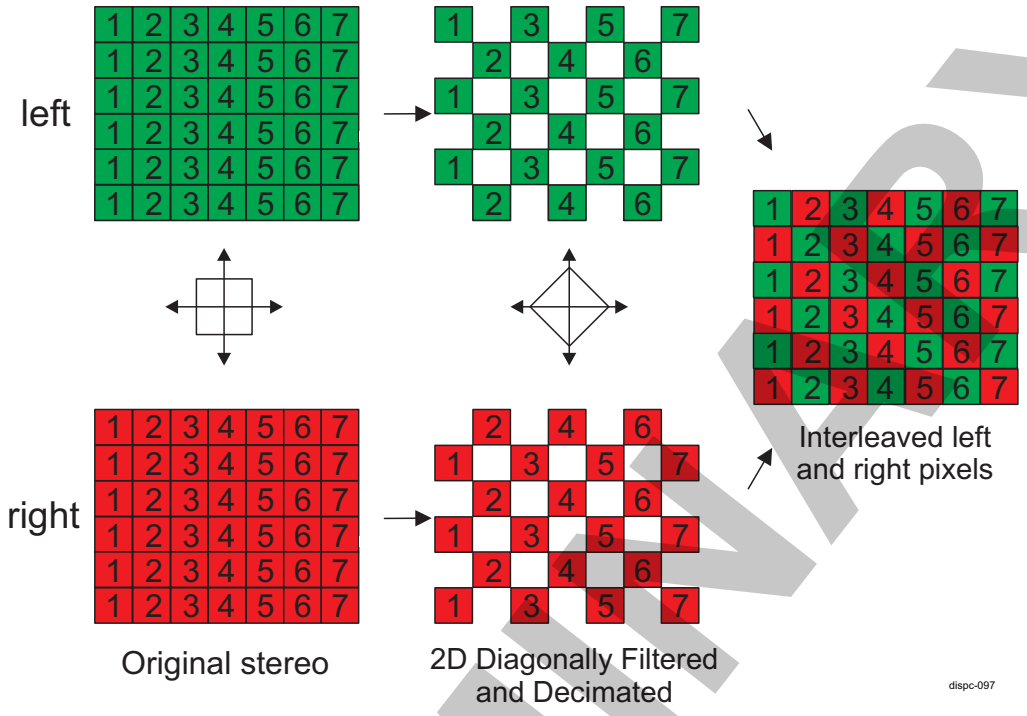
The sub-sampling required on the left and the right frame is complementary. This sampling pattern is also defined in the HDMI 3D Specification 1.4a as two Quincunx matrices. The format is configured from DISPC_GFX_ATTRIBUTES[20:18] SUBSAMPLINGPATTERN, DISPC_VID1_ATTRIBUTES2[11:9], DISPC_VID2_ATTRIBUTES2[11:9], DISPC_VID3_ATTRIBUTES2[11:9] SUBSAMPLINGPATTERN with the following possible configuration:

- 0x0: All pixels from the pipes are used. No sub-sampling.
- 0x1: Quincunx Matrix Odd-position sub-sampling is used.
- 0x2: Quincunx Matrix Even-position sub-sampling is used.
- 0x3 to 0x7: Reserved

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-88. DISPC Illustration of DLP 3D Format



The following limitations apply to the DLP 3D Format :

- Even z-order pipes can have only sub-sampling = 0x1. Odd z-order pipes can only have sub-sampling = 0x2.

10.2.4.15 DISPC Shadow Registers

Some DISPC registers are termed *shadow registers*. A shadow register change has no direct effect on the configuration of the DISPC. The registers are shadow registers let software change the values of the registers at any time. When all the registers for a given configuration are into the registers, software must set 1 bit only to validate the configuration. When hardware reaches the end of the current frame and sees that the bit field has been set by software, the new configuration is now the configuration used by the hardware.

NOTE: As a general rule, all shadow registers are updated with the value of their shadows when:

- The interface is enabled.
- The GO bit field of the pipeline, with which the register is associated, is set and the output sync is active.

The bits enabling the hardware to use the new configuration are:

- DISPC_CONTROL1[5] GOLCD bit for all the registers associated to the LCD1 output, and for all registers of WB and DMA, if the LCD1 channel is captured. The update of the registers of the WB and DMA is further delayed by the DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNTER bit field or done when the next frame is captured (the DISPC_WB_ATTRIBUTES[26:24] CAPTUREMODE bit field must be different from 0). The update of the registers occurs at the VFP start period.
- DISPC_CONTROL1[6] GOTV bit for all the registers associated to the TV output, and for all registers of WB and DMA, if the TV channel is captured. The update of the registers of the WB and DMA is further delayed by the DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNTER bit field or done when the next frame is captured (the DISPC_WB_ATTRIBUTES[26:24] CAPTUREMODE bit field must be different from 0). The update of the registers occurs at the external EVSYNC.
- DISPC_CONTROL2[5] GOLCD bit for all the registers associated to the LCD2 output, and for all registers of WB and DMA, if the LCD2 channel is captured. The update of the registers of the WB and

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

DMA is further delayed by the DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNTER bit field or done when the next frame is captured (the DISPC_WB_ATTRIBUTES[26:24] CAPTUREMODE bit field must be different from 0). The update of the registers occurs at the VFP start period.

- DISPC_CONTROL3[5] GOLCD bit for all the registers associated to the LCD3 output, and for all registers of WB and DMA, if the LCD3 channel is captured. The update of the registers of the WB and DMA is further delayed by the DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNTER bit field or done when the next frame is captured (the DISPC_WB_ATTRIBUTES[26:24] CAPTUREMODE bit field must be different from 0). The update of the registers occurs at the VFP start period.
- DISPC_WB_ATTRIBUTES[0] ENABLE bit for all the registers associated to the WB, if the transfer memory-to-memory is not associated with a channel out.
- The DISPC_CONTROL2[6] GOWB bit and the [5] GOLCD and [6] GOTV bits in the DISPC_CONTROL1/DISPC_CONTROL2 registers, combined with the synchronization event of the channel output selected for write back. This applies to all registers associated with the selected channel out and further delayed by the setting in the DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNT bit field, for all registers of the write back and DMA. The GOWB bit is required to be set only in WB capture mode; it is not required when WB memory-to-memory mode is used.

NOTE: Before setting the GOLCD, GOTV, or GOWB bits, the user must ensure that the bits are cleared. The hardware resets the bits when the update completes.

Table 10-54 lists the shadow registers. Registers that do not have a mark in any column are not shadowed.

Table 10-54. DISPC Shadow Registers

10.2.5 DISPC Programming Guide

10.2.5.1 DISPC Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

10.2.5.1.1 DISPC Global Initialization

10.2.5.1.1.1 DISPC Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the DISPC module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the DISPC. For more information, see Section 10.2.3, *DISPC Integration*, and , *DISPC Environment*.

Table 10-55. DISPC Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. See , *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
Control module	Module-specific pad muxing and configuration must be set in the control module. See , *PAD Functional Multiplexing and Configuration*, in *Chapter 18, Control Module*.
MPU INTC or DSP INTC	MPU and/or DSP interrupt controller configuration must be done to enable the interrupts from the DISPC. See , *Interrupt Controllers Overview*, in Chapter 17, *Interrupt Controllers*.
Interconnect	For more information about interconnect configuration, see , L3 Interconnect, in Chapter 14, *Interconnects*.

10.2.5.1.2 DISPC Operational Modes Configuration

Table 10-56 lists the steps to configure the operational modes in the DISPC.

Table 10-56. DISPC Configuration

Step	Register/Bit Field/Programming Model
For a GFX pipeline configuration	
Configure the GFX DMA channel.	See Table 10-57.
Configure the GFX pipeline.	See Table 10-60.
Configure the LCD or TV output.	For LCD output, see Table 10-78.
	For TV output, see Table 10-85.
For a Video pipeline configuration	
Configure the video DMA channel.	See Table 10-58.
Configure the video pipeline.	See Table 10-65.
Configure the LCD or TV output.	For LCD output, see Table 10-78.
	For TV output, see Table 10-85.
For a WB pipeline configuration	
Configure the WB DMA channel.	See Table 10-59.
Configure the WB pipeline.	For video pipelines, see Table 10-73.

10.2.5.1.2.1 DISPC DMA Configuration

10.2.5.1.2.1.1 DISPC Main Sequence – DISPC DMA Channel Configuration

This procedure describes the parameters of the GFX, video, and WB DMA channel parameters (see Table 10-57 through Table 10-59, respectively).

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

Table 10-57. DISPC Configure the GFX DMA Channel

Step	Register/Bit Field/Programming Model	Value
Set the base address for RGB pixel format or BITMAP component format according to memory access type, rotation, mirroring (see Section 10.2.4.6, *DISPC DMA Engine*).	DISPC_GFX_BA_j[31:0] BA	0x—
Set the rotation flag.	DISPC_GFX_ATTRIBUTES[13:12] ROTATION	0x–
Set the number of bytes to increment at the end of the row.	DISPC_GFX_ROW_INC[31:0] ROWINC	0x–
Set the number of bytes to increment between two pixels.	DISPC_GFX_PIXEL_INC[7:0] PIXELINC	0x–
Determine the FIFO preload mode.	DISPC_GFX_ATTRIBUTES[11] BUFPRELOAD	0x–
Set the preload value.	DISPC_GFX_PRELOAD[11:0] PRELOAD	0x–
Determine the burst type.	DISPC_GFX_ATTRIBUTES[29] BURSTTYPE	0x–
Set the burst size.	DISPC_GFX_ATTRIBUTES[7:6] BURSTSIZE	0x–
Set the high level of DMA FIFO threshold.	DISPC_GFX_BUF_THRESHOLD[31:16] BUFHIGHTRESHOLD	0x–
Set the low level of DMA FIFO threshold.	DISPC_GFX_BUF_THRESHOLD[15:0] BUFLOWTRESHOLD	0x–
Enable self-refresh.	DISPC_GFX_ATTRIBUTES[24] SELFREFRESH	0x–
Select priority over the other pipeline.	DISPC_GFX_ATTRIBUTES[23] ARBITRATION	0x–

Table 10-58. DISPC Configure the Video DMA Channel

Step	Register/Bit Field/Programming Model	Value
Set the base address for RGB pixel format or Y component format according to memory access type, rotation, mirroring (seeSection 10.2.4.6, *DISPC DMA Engine*).	DISPC_VIDp_BA_j[31:0] BA	0x—
Set the base address for Cb and Cr components according to memory access type, rotation, mirroring (seeSection 10.2.4.6, *DISPC DMA Engine*)[(1)].	DISPC_VIDp_BA_UV_j[31:0] BA	0x—
Set the rotation flag.	DISPC_VIDp_ATTRIBUTES[13:12] ROTATION	0x–
Set the number of bytes to increment at the end of the row.	DISPC_VIDp_ROW_INC[31:0] ROWINC	0x–
Set the number of bytes to increment between two pixels.	DISPC_VIDp_PIXEL_INC[7:0] PIXELINC	0x–
Set the X original image size.	DISPC_VIDp_PICTURE_SIZE[10:0] MEMSIZEX	0x–
Set the Y original image size.	DISPC_VIDp_PICTURE_SIZE[27:16] MEMSIZEY	0x–
Determine the FIFO preload mode.	DISPC_VIDp_ATTRIBUTES[19] BUFPRELOAD	0x–
Set the preload value.	DISPC_VIDp_PRELOAD[11:0] PRELOAD	0x–
Determine the burst type.	DISPC_VIDp_ATTRIBUTES[29] BURSTTYPE	0x–
Set the burst size.	DISPC_VIDp_ATTRIBUTES[15:14] BURSTSIZE	0x–
Set the high level of DMA FIFO threshold.	DISPC_VIDp_BUF_THRESHOLD[31:16] BUFHIGHTRESHOLD	0x–
Set the low level of DMA FIFO threshold.	DISPC_VIDp_BUF_THRESHOLD[15:0] BUFLOWTRESHOLD	0x–
Enable self-refresh.	DISPC_VIDp_ATTRIBUTES[24] SELFREFRESH	0x–
Select priority over the other pipeline.	DISPC_VIDp_ATTRIBUTES[23] ARBITRATION	0x–

(1) Applicable only for YUV pixel format

10.2.5.1.2.2 DISPC GFX Pipeline Configuration

10.2.5.1.2.2.1 DISPC Main Sequence – Configure the GFX Pipeline

This procedure details the steps for a GFX pipeline configuration (see Table 10-60).

Table 10-60. DISPC Configure the GFX Pipeline

Step	Register/Bit Field/Programming Model	Value
Configure the GFX window.	See Table 10-61.	
Configure the GFX pipeline processing.	See Table 10-62.	
Configure the GFX pipeline layer output.	See Table 10-64.	
Validate the GFX configuration according to outputs associated to the pipeline.	DISPC_CONTROL1[5] GOLCD	
	DISPC_CONTROL2[5] GOLCD	
	DISPC_CONTROL2[6] GOWB	
	DISPC_CONTROL1[6] GOTV	
Enable the GFX pipeline.	DISPC_GFX_ATTRIBUTES[0] ENABLE	0x1

10.2.5.1.2.2.2 DISPC Subsequence – Configure the GFX Window

This subsequence describes the parameters of the image to be displayed on the LCD panel (see Table 10-61).

Table 10-61. DISPC Configure the GFX Window

Step	Register/Bit Field/Programming Model	Value
Select the format of image.	DISPC_GFX_ATTRIBUTES[4:1] FORMAT	0x–
Set the X size of image to be displayed onto LCD panel.	DISPC_GFX_SIZE[11:0] SIZEX	0x–
Set the Y size of image to be displayed onto LCD panel.	DISPC_GFX_SIZE[27:16] SIZEY	0x–
Set the X position of image in respect to LCD panel.	DISPC_GFX_POSITION[10:0] POSX	0x–
Set the Y position of image in respect to LCD panel.	DISPC_GFX_POSITION[26:16] POSY	0x–

10.2.5.1.2.2.3 DISPC Subsequence – Configure the GFX Pipeline Processing

This subsequence describes the steps to configure the GFX pipeline processing in the DISPC (seeTable 10-62).

Table 10-62. DISPC Configure the GFX Pipeline Processing

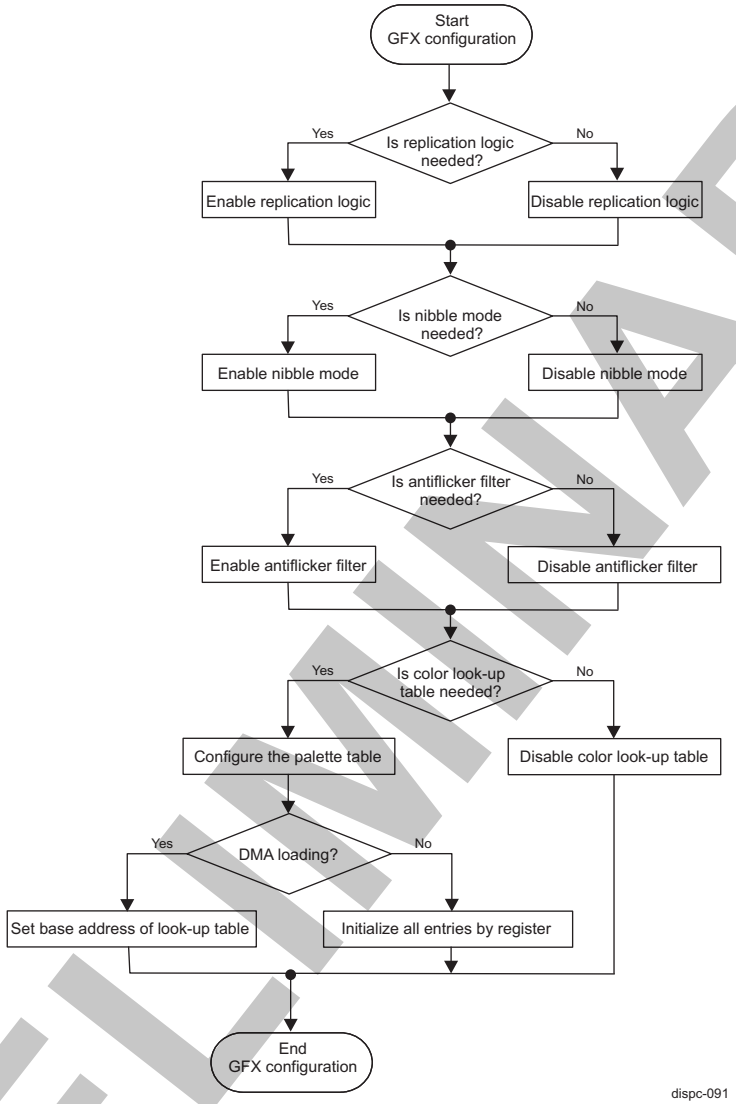
Step	Register/Bit Field/Programming Model	Value
Enable replication logic.	DISPC_GFX_ATTRIBUTES[5] REPLICATIONENABLE	0x1
Enable nibble mode.	DISPC_GFX_ATTRIBUTES[9] NIBBLEMODE	0x1
Enable antiflicker filter.	DISPC_GFX_ATTRIBUTES[24] ANTIFLICKER	0x1
Configure the palette table.	See Table 10-63.	0x–

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-89 shows the configuration of the DISPC video pipeline processing.

Figure 10-89. DISPC Video Pipeline Processing Configuration



10.2.5.1.2.2.4 DISPC Subsequence – Configure the Palette Table

This subsequence describes the settings to configure the CLUT as a palette for the GFX pipeline (see Table 10-63).

NOTE:

- Software must ensure there is no visible effect when modifying the table because it is not under hardware control. The synchronization done using the DMA engine inside the DISPC to load the table when it is not used for displaying the picture on the screen is not present for this mode.
- If the GFX pipeline is in BITMAP pixel format, gamma corrections are not available for LCD1.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 10-63. DISPC Configure the Palette Table

Step	Register/Bit Field/Programming Model	Value
Set look-up table as palette table.	DISPC_CONFIG1[3] PALETTEGAMMATABLE	0x0
Select the load mode of the palette look-up table.	DISPC_CONFIG1[2:1] LOADMODE	0x–
DMA loading		
Set base address of look-up table.	DISPC_GFX_TABLE_BA[31:0] TABLEBA	0x–
Initialize all entries by register		
Initialize all entries for the palette table by setting the table index and the RGB values associated to this index.	DISPC_GAMMA_TABLE0[31:24][23:16][15:8][7:0], INDEX, VALUE_R, VALUE_G, VALUE_B	0x–

10.2.5.1.2.5 DISPC Subsequence – Configure the GFX Pipeline Layer Output

This subsequence describes the video layer settings available at the pipeline level necessary when using the overlay manager (see Table 10-64).

Table 10-64. DISPC Configure the GFX Pipeline Layer Output

Step	Register/Bit Field/Programming Model	Value
Set the LCD/TV output.	DISPC_GFX_ATTRIBUTES[8] CHANNELOUT	0x–
If DISPC_GFX_ATTRIBUTES[8] = 0, set the LCD output.	DISPC_GFX_ATTRIBUTES[31:30] CHANNELOUT2	0x–
Set the Z-order priority of the layer for overlay manager.	DISPC_GFX_ATTRIBUTES[27:26] ZORDER	0x–
Enable the video pipeline Z-order.	DISPC_GFX_ATTRIBUTES[25] ZORDERENABLE	0x–
Set the Global Alpha value for the alpha blender unit.	DISPC_GLOBAL_ALPHA[7:0] GFXGLOBALALPHA	0x–

10.2.5.1.2.3 DISPC Video Pipeline Configuration

10.2.5.1.2.3.1 DISPC Main Sequence – Configure the Video Pipeline

This sequence describes the steps to configure the video pipeline (see Table 10-65).

Table 10-65. DISPC Configure the Video Pipeline

Step	Register/Bit Field/Programming Model	Value
Configure the video window.	See Table 10-66.	
Configure the video pipeline processing.	See Table 10-67.	
Configure the video pipeline layer output.	See Table 10-72.	
Validate the video configuration according to outputs associated to the pipeline.	DISPC_CONTROL1[5] GOLCD	
	DISPC_CONTROL2[5] GOLCD	
	DISPC_CONTROL2[6] GOWB	
	DISPC_CONTROL1[6] GOTV	
Enable video pipeline.	DISPC_VIDp_ATTRIBUTES[0] ENABLE	0x1

10.2.5.1.2.3.2 DISPC Subsequence – Configure the Video Window

This subsequence describes the parameters of the image to be displayed on the LCD panel (see Table 10-66).

PRELIMINARY

Table 10-66. DISPC Configure the Video Window

Step	Register/Bit Field/Programming Model	Value
Select the format of image.	DISPC_VIDp_ATTRIBUTES[4:1] FORMAT	0x–
Set the X size of image to be displayed onto LCD panel.	DISPC_VIDp_SIZE[11:0] SIZEX	0x–
Set the Y size of image to be displayed onto LCD panel.	DISPC_VIDp_SIZE[27:16] SIZEY	0x–
Set the X position of image in respect to LCD panel.	DISPC_VIDp_POSITION[10:0] POSX	0x–
Set the Y position of image in respect to LCD panel.	DISPC_VIDp_POSITION[26:16] POSY	0x–

10.2.5.1.2.3.3 DISPC Subsequence – Configure the Video Pipeline Processing

This subsequence describes the steps to configure video pipeline processing (see Table 10-67 and Figure 10-90).

Table 10-67. DISPC Configure the Video Pipeline Processing

Step	Register/Bit Field/Programming Model	Value
Select the video pipeline configuration 1 or 2.	DISPC_VIDp_ATTRIBUTES2[8] YUVCHROMARESAMPLING	0x–
Enable/disable replication logic(1).	DISPC_VIDp_ATTRIBUTES[10] REPLICATIONENABLE	0x1
Configure the VC-1 range mapping(1).	See Section 10.2.5.1.2.3.4.	
Configure the video color space conversion(1).	See Section 10.2.5.1.2.3.5.	
Configure the video scaler unit(1).	See Section 10.2.5.1.2.3.6.	

(1) This module configuration can be optional depending on:
- The video mode configuration selected. See Figure 10-90.
- The video format and application needs

10.2.5.1.2.3.7 DISPC Subsequence – Configure the Video Pipeline Layer Output

This subsequence describes the video layer settings available at the pipeline level necessary when using the overlay manager (see Table 10-72).

Table 10-72. DISPC Configure the Video Pipeline Layer Output

Step	Register/Bit Field/Programming Model	Value
Set the LCD/TV output.	DISPC_VIDp_ATTRIBUTES[16] CHANNELOUT	0x–
If DISPC_VIDp_ATTRIBUTES[16] = 0, set the LCD output.	DISPC_VIDp_ATTRIBUTES[31:30] CHANNELOUT2	0x–
Set the Z-order priority of the layer for overlay manager.	DISPC_VIDp_ATTRIBUTES[27:26] ZORDER	0x–
Enable the video pipeline Z-order.	DISPC_VIDp_ATTRIBUTES[25] ZORDERENABLE	0x–
Set the Global Alpha value for the alpha blender unit.	DISPC_GLOBAL_ALPHA[31:24][23:16][15:8] VID3GLOBALALPHA, VID2GLOBALALPHA, VID1GLOBALALPHA	0x–

10.2.5.1.2.4 DISPC WB Pipeline Configuration

10.2.5.1.2.4.1 DISPC Main Sequence – Configure the WB Pipeline

This procedure describes the steps to configure the WB pipeline (see Table 10-73).

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 10-73. DISPC Configure the WB Pipeline

Step	Register/Bit Field/Programming Model	Value
Configure the capture window.	See Table 10-74.	
Configure the WB scaler unit.	See Table 10-75.	
Enable truncation logic to match pixel size defined in the format of image DISPC_WB_ATTRIBUTES[4:1] FORMAT.	DISPC_WB_ATTRIBUTES[10] TRUNCATIONENABLE	0x–
If DISPC_WB_ATTRIBUTES[10] !=, configure the WB color space conversion unit.	See Table 10-77.	
Validate the configuration according to the registers modification.	DISPC_CONTROL2[6] GOWB	
Enable WB pipeline.	DISPC_WB_ATTRIBUTES[0] ENABLE	0x1

10.2.5.1.2.4.2 DISPC Subsequence – Configure the Capture Window

This subsequence describes the parameters of the image to be captured in the system memory (see Table 10-74).

Table 10-74. DISPC Configure the Capture Window

Step	Register/Bit Field/Programming Model	Value
Set the input source.	DISPC_WB_ATTRIBUTES[18:16] CHANNELIN	0x–
Select the format of image.	DISPC_WB_ATTRIBUTES[4:1] FORMAT	0x–
Set the X size of image to be captured.	DISPC_WB_SIZE[10:0] SIZEX	0x–
Set the Y size of image to be captured.	DISPC_WB_SIZE[10:0] SIZEY	0x–

10.2.5.1.2.4.3 DISPC Subsequence – Configure the WB Scaler Unit

This subsequence configures the scaler unit. Table 10-75 is applicable for RGB pixel format. Table 10-75 and Table 10-76 are applicable for YUV pixel format.

Table 10-75. DISPC Configure the WB Scaler Unit for RGB Pixel Formats or Y Component

Step	Register/Bit Field/Programming Model	Value
Configure horizontal scaling		
Set the horizontal resizing ratio.	DISPC_WB_FIR[12:0] FIRHINC	0x–
Set the horizontal FIR coefficients.	DISPC_WB_FIR_COEF_H_i[31:24][23:16][15:8][7:0] FIRHC3, FIRHC2, FIRHC1, FIRHC0	0x–
	DISPC_WB_FIR_COEF_HV_i[7:0] FIRHC4	0x–
Set the horizontal accumulators value.	DISPC_WB_ACCU_j[10:0] HORIZONTALACCU	0x–
Configure vertical scaling		
Select number of vertical taps.	DISPC_WB_ATTRIBUTES[21] VERTICALTAPS	0x–
Set the vertical resizing ratio.	DISPC_WB_FIR[28:16] FIRVINC	0x–
Set the vertical FIR coefficients for RGB pixel format or Y component.	DISPC_WB_FIR_COEF_HV_i[31:24][23:16][15:8] FIRVC2, FIRVC1, FIRVC0	0x–
	Only for 5-taps vertical: DISPC_WB_FIR_COEF_V_i[15:8][7:0] FIRVC22, FIRVC00	0x–
Set the vertical accumulators value for RGB pixel format or Y component.	DISPC_WB_ACCU_j[26:16] VERTICALACCU	0x–
Enable horizontal and vertical scaler unit.	DISPC_WB_ATTRIBUTES[6:5] RESIZEENABLE	0x–

10.2.5.1.2.5.2 DISPC Subsequence – Configure the Overlay Manager

This subsequence describes the overlay manager settings and transparency color key configuration (see Table 10-79).

Table 10-79. DISPC Configure the LCD Overlay Manager

Step	Register/Bit Field/Programming Model	Value
Set the LCD panel background color.	DISPC_DEFAULT_COLORo[23:0] DEFAULTCOLOR	0x–
Enable/disable overlay optimization.	DISPC_CONTROLo[12] OVERLAYOPTIMIZATION	0x–
Enable the alpha blender(1).	DISPC_CONFIG1[18] LCDALPHABLENDERENABLE	0x1
Configure the transparency color key		
Set source or destination transparency color key mode.	DISPC_CONFIGo[11] TCKLCDSELECTION	0x–
Set the transparency color value.	DISPC_TRANS_COLORo[23:0] TRANSCOLORKEY	0x–
Enable transparency color key mode.	DISPC_CONFIGo[10] TCKLCDENABLE	0x–

(1) Backward compatibility with OMAP34xx available only for LCD1

10.2.5.1.2.5.3 DISPC Subsequence – Configure the Gamma Table for Gamma Correction

This subsequence describes the settings for configuring the gamma correction for LCD1, LCD2, and LCD3 (see Table 10-80 through Table 10-82, respectively).

NOTE:

- Software must ensure there is no visible effect when modifying the table because it is not under hardware control. The synchronization done using the DMA engine inside the DISPC to load the table when it is not used to display the picture on the screen is not present for this mode.
- If the GFX pipeline is in BITMAP pixel format, gamma corrections are not available for LCD1.

Table 10-80. DISPC Configure the Gamma Table for LCD1

Step	Register/Bit Field/Programming Model	Value
Initialize all entries for the gamma table by setting the table index and the RGB values associated to this index.	DISPC_GAMMA_TABLE0[31:24][23:16][15:8][7:0], INDEX, VALUE_R, VALUE_G, VALUE_B	0x–
Set look up table as gamma table.	DISPC_CONFIG1[3] PALETTEGAMMATABLE	0x1
Select the load mode of the gamma look-up table.	DISPC_CONFIG1[2:1] LOADMODE	0x–

Table 10-81. DISPC Configure the Gamma Table for LCD2

Step	Register/Bit Field/Programming Model	Value
Enable Gamma table for LCD2 and TV.	DISPC_CONFIG2[9] GAMATABLEENABLE	0x1
Initialize all entries for the gamma table by setting the table index and the RGB values associated to this index.	DISPC_GAMMA_TABLE2[31:24][23:16][15:8][7:0], INDEX, VALUE_R, VALUE_G, VALUE_B	0x–

Table 10-82. DISPC Configure the Gamma Table for LCD3

Step	Register/Bit Field/Programming Model	Value
Enable Gamma table for LCD3 and TV.	DISPC_CONFIG3[9] GAMATABLEENABLE	0x1
Initialize all entries for the gamma table by setting the table index and the RGB values associated to this index.	DISPC_GAMMA_TABLE3[31:24][23:16][15:8][7:0], INDEX, VALUE_R, VALUE_G, VALUE_B	0x–

10.2.5.1.2.5.4 DISPC Subsequence – Configure the Color Phase Rotation

Table 10-83 describes the settings for the CPR unit (see Table 10-83).

Table 10-83. DISPC Configure the Color Phase Rotation

Step	Register/Bit Field/Programming Model	Value
Set the Red coefficients.	DISPC_CPRo_COEF_R [31:22][20:11][9:0] RR, RG, RB	0x–
Set the Green coefficients	DISPC_CPRo_COEF_G [31:22][20:11][9:0] GR, GG, GB	0x–
Set the Blue coefficients.	DISPC_CPRo_COEF_B [31:22][20:11][9:0] BR, BG, BB	0x–
Disable the CPR unit in RGB to YUV conversion.	DISPC_CONFIGo[24] COLORCONVENABLE	0x0
Enable the CPR unit.	DISPC_CONFIGo[15] CPR	0x1

10.2.5.1.2.5.5 DISPC Subsequence – Configure the LCD Panel Timings and Parameters

This subsequence describes the setting for horizontal and vertical synchronization and signal polarity (see Table 10-84).

Table 10-84. DISPC Configure the LCD Panel Timings and Parameters

Step	Register/Bit Field/Programming Model	Value
Configure spatial/temporal dithering		
Select spatial/temporal number of frames.	DISPC_CONTROLo[31:30] SPATIALTEMPORALDITHERINGFRAMES	0x–
Enable spatial/temporal dithering.	DISPC_CONTROLo[7] STDITHERENABLE	0x–
Configure AC-bias		
Configure the VSYNC, HSYNC and AC bias polarity.	DISPC_POL_FREQo	0x–
Configure the gating of AC bias polarity.	DISPC_CONFIGo[8] ACBIASGATED	0x–
Configure the AC bias polarity.	DISPC_POL_FREQo[15] IEO	0x–
Set the AC bias frequency.	DISPC_POL_FREQo[7:0] ACB	0x–
Set the number of AC bias transitions per interrupt.	DISPC_POL_FREQo[11:8] ACBI	0x–
Configure the pixel clock		
Set the DISPC logic clock divisor.	DISPC_DIVISORo[23:16] LCD	0x–
Set the pixel clock divisor.	DISPC_DIVISORo[7:0] PCD	0x–
Configure the gating of pixel clock.	DISPC_CONFIGo[5] PIXELCLOCKGATED	0x–
Configure the data		
Set the pixel clock edge to drive data output.	DISPC_POL_FREQo[14] IPC	0x–
Configure the gating of data output.	DISPC_CONFIGo[4] PIXELDATAGATED	0x–
Set the data output mode.	DISPC_CONFIGo[22] OUTPUTMODEENABLE	0x–
Configure the panel parameters		
Set the vertical TV size.	DISPC_SIZE_LCDo[27:16] LPP	0x–
Set the horizontal TV size.	DISPC_SIZE_LCDo[11:0] PPL	0x–
Set the panel type.	DISPC_CONTROLo[3] STNTFT	0x–
Configure the refresh rate and horizontal and vertical parameters		
Set the vertical synchronization timing.	DISPC_TIMING_Vo[31:20][19:8][7:0], VBP, VFP, VSW	0x–
Configure the VSYNC polarity.	DISPC_POL_FREQo[12] IVS	0x–
Configure the gating of VSYNC.	DISPC_CONFIGo[7] VSYNCGATED	0x–
Set the horizontal synchronization timing.	DISPC_TIMING_Ho[31:20][19:8][7:0], HBP, HFP, HSW	0x–
Configure the HSYNC polarity.	DISPC_POL_FREQo[13] IHS	0x–
Configure the gating of HSYNC.	DISPC_CONFIGo[6] HSYNCGATED	0x–
Set the opposition of HSYNC and VSYNC driving.	DISPC_POL_FREQo[17] ONOFF	0x–

Step	Register/Bit Field/Programming Model	Value
If DISPC_POL_FREQo[17] = 1, set the pixel clock edge to drive HSYNC and VSYNC.	DISPC_POL_FREQo[16] RF	0x–
Set the alignment of HSYNC and VSYNC.	DISPC_POL_FREQo[18] ALIGN	0x–

10.2.5.1.2.6 DISPC TV Output Configuration

10.2.5.1.2.6.1 DISPC Main Sequence – Configure the TV Output

This procedure describes the TV output configuration (see Table 10-85).

Table 10-85. DISPC Configure the TV Output

Step	Register/Bit Field/Programming Model
Configure the TV overlay manager.	See Table 10-86.
Configure the gamma table for gamma correction.	See Table 10-87.
Configure the TV panel timings and parameters.	See Table 10-88.
Validate the TV output configuration accordingly.	DISPC_CONTROL1[6] GOTV
Enable the TV output.	DISPC_CONTROL1[1] TVENABLE

10.2.5.1.2.6.1.1 DISPC Subsequence – Configure the TV Overlay Manager

This subsequence describes the overlay manager settings and transparency color key configuration (see Table 10-86).

Table 10-86. DISPC Configure the TV Overlay Manager

Step	Register/Bit Field/Programming Model	Value
Set the TV panel background color.	DISPC_DEFAULT_COLOR1[23:0] DEFAULTCOLOR	0x–
Enable/disable overlay optimization.	DISPC_CONTROL2[13] TVOVERLAYOPTIMIZATION	0x–
Enable the alpha blender(1).	DISPC_CONFIG1[19] TVALPHABLENDERENABLE	0x1
Configure the transparency color key		
Set source or destination transparency color key mode.	DISPC_CONFIG1[13] TCKTVSELECTION	0x–
Set the transparency color value.	DISPC_TRANS_COLOR1[23:0] TRANSCOLORKEY	0x–
Enable transparency color key mode.	DISPC_CONFIG1[10] TCKTVENABLE	0x–

(1) Backward compatibility with OMAP34xx

10.2.5.1.2.6.1.2 DISPC Subsequence – Configure the Gamma Table for Gamma Correction

This subsequence describes the steps to configure the gamma table for gamma correction (see Table 10-87).

NOTE: Software must ensure there is no visible effect when modifying the table because it is not under hardware control. The synchronization done using the DMA engine inside the DISPC to load the table when it is not used for displaying the picture on the screen is not present for this mode.

Table 10-87. DISPC Configure the Gamma Table for TV Output

Step	Register/Bit Field/Programming Model	Value
Enable Gamma table for LCD2 and TV.	DISPC_CONFIG1[9] GAMATABLEENABLE	0x1
Initialize all entries for the gamma table by setting the table index and the RGB values. For more information, see Section 10.2.4.13.2, *Gamma Correction Unit*.	DISPC_GAMMA_TABLE2[31][29:20][19:10][9:0] INDEX, VALUE_R, VALUE_G, VALUE_B	0x–

10.2.5.1.2.6.1.3 DISPC Subsequence – Configure the TV Panel Timings and Parameters

This subsequence describes the settings for horizontal and vertical synchronization and signal polarity (see Table 10-88).

Table 10-88. DISPC Configure the TV Panel Timings and Parameters

Step	Register/Bit Field/Programming Model	Value
Set the hold time for TV data outputs.	DISPC_CONFIG1[19:17]	0x–
Set the vertical TV size.	DISPC_SIZE_TV[27:16] LPP	See Table 10-53 for HD standards.
Set the horizontal TV size.	DISPC_SIZE_TV[11:0] PPL	

10.2.6 DISPC Use Cases and Tips

10.2.6.1 DISPC Hardware Cursor

The video layer or graphics layer can be used to display the hardware cursor. The encoded pixel data for the cursor image are in one of the following formats if the source transparency color key is used:

- xRGB12-4444
- ARGB16-4444
- RGBx12-4444
- RGBA16-4444
- ARGB16-1555
- RGB16-565
- RGB24-888
- xRGB24-88888
- RGBA32-8888
- BGRA32-8888
- ARGB32-8888

Otherwise, any pixel format can be used for the cursor image, considering the limitation in terms of pixels supported by the pipeline used to display the cursor image. To display a nonrectangle cursor, the transparency color key or alpha blending (pixel alpha blending) can be used (see Section 10.2.4.12.1.3, *DISPC Transparency Color Keys*). Global alpha blending can be used in addition to the transparency source color key to create a fading effect when the cursor (with a nonrectangle shape) appears and disappears on the screen. The image of the cursor can be stored entirely inside the DMA buffer to use the self-refresh mode (see Section 10.2.4.6.8.2, *DISPC DMA Ultralow-Power Mode*). In that case, the image is loaded once and then displayed without accessing the system memory for loading the image for each frame. This saves bandwidth on interconnect and memory.

DISPC_VID1_BA_UV_j	Base address of UV components for video pipeline 1
DISPC_VID2_BA_UV_j	Base address of UV components for video pipeline 2
DISPC_VID3_BA_UV_j	Base address of UV components for video pipeline 3

Table 10-92. DISPC_VIDp_POSITION Logical Register Mapping

Hardware Register	Description
DISPC_VID1_POSITION	Position of the video window 1
DISPC_VID2_POSITION	Position of the video window 2
DISPC_VID3_POSITION	Position of the video window 3

Table 10-93. DISPC_VIDp_SIZE Logical Register Mapping

Hardware Register	Description
DISPC_VID1_SIZE	Size of the video window 1
DISPC_VID2_SIZE	Size of the video window 2
DISPC_VID3_SIZE	Size of the video window 3

Table 10-94. DISPC_VIDp_ATTRIBUTES Logical Register Mapping

Hardware Register	Description
DISPC_VID1_ATTRIBUTES	Configuration of the video pipeline 1
DISPC_VID2_ATTRIBUTES	Configuration of the video pipeline 2
DISPC_VID3_ATTRIBUTES	Configuration of the video pipeline 3

Table 10-95. DISPC_VIDp_ATTRIBUTES2 Logical Register Mapping

Hardware Register	Description
DISPC_VID1_ATTRIBUTES2	Configuration of the video pipeline 1
DISPC_VID2_ATTRIBUTES2	Configuration of the video pipeline 2
DISPC_VID3_ATTRIBUTES2	Configuration of the video pipeline 3

PRELIMINARY

Table 10-96. DISPC_VIDp_BUF_THRESHOLD Logical Register Mapping

Hardware Register	Description
DISPC_VID1_BUF_THRESHOLD	Configuration of the buffer for the video pipeline 1
DISPC_VID2_BUF_THRESHOLD	Configuration of the buffer for the video pipeline 2
DISPC_VID3_BUF_THRESHOLD	Configuration of the buffer for the video pipeline 3

Table 10-97. DISPC_VIDp_ROW_INC Logical Register Mapping

Hardware Register	Description
DISPC_VID1_ROW_INC	Configuration of the row increment for the video pipeline 1
DISPC_VID2_ROW_INC	Configuration of the row increment for the video pipeline 2
DISPC_VID3_ROW_INC	Configuration of the row increment for the video pipeline 3

Table 10-98. DISPC_VIDp_PIXEL_INC Logical Register Mapping

Hardware Register	Description
DISPC_VID1_PIXEL_INC	Configuration of the pixel increment for the video pipeline 1
DISPC_VID2_PIXEL_INC	Configuration of the pixel increment for the video pipeline 2
DISPC_VID3_PIXEL_INC	Configuration of the pixel increment for the video pipeline 3

Table 10-99. DISPC_VIDp_FIR Logical Register Mapping

Hardware Register	Description
DISPC_VID1_FIR	Configuration of the scaler for the video pipeline 1
DISPC_VID2_FIR	Configuration of the scaler for the video pipeline 2
DISPC_VID3_FIR	Configuration of the scaler for the video pipeline 3

Table 10-100. DISPC_VIDp_PICTURE_SIZE Logical Register Mapping

Hardware Register	Description
DISPC_VID1_PICTURE_SIZE	Size of the video window 1 before processing
DISPC_VID2_PICTURE_SIZE	Size of the video window 2 before processing
DISPC_VID3_PICTURE_SIZE	Size of the video window 3 before processing

Table 10-101. DISPC_VIDp_ACCU_j Logical Register Mapping

Hardware Register	Description
DISPC_VID1_ACCU_j	Configuration of the accumulator for the video pipeline 1
DISPC_VID2_ACCU_j	Configuration of the accumulator for the video pipeline 2
DISPC_VID2_ACCU_j	Configuration of the accumulator for the video pipeline 3

Table 10-102. DISPC_VIDp_FIR_COEF_H_i Logical Register Mapping

Hardware Register	Description
DISPC_VID1_FIR_COEF_H_i	Configuration of the horizontal scaling coefficients for the video pipeline 1
DISPC_VID2_FIR_COEF_H_i	Configuration of the horizontal scaling coefficients for the video pipeline 2
DISPC_VID3_FIR_COEF_H_i	Configuration of the horizontal scaling coefficients or the video pipeline 3

PRELIMINARY

Table 10-103. DISPC_VIDp_FIR_COEF_HV_i Logical Register Mapping

Hardware Register	Description
DISPC_VID1_FIR_COEF_HV_i	Configuration of the horizontal scaling coefficients for the video pipeline 1
DISPC_VID2_FIR_COEF_HV_i	Configuration of the horizontal scaling coefficients for the video pipeline 2
DISPC_VID3_FIR_COEF_HV_i	Configuration of the horizontal scaling coefficients for the video pipeline 3

Table 10-104. DISPC_VIDp_FIR_COEF_V_i Logical Register Mapping

Hardware Register	Description
DISPC_VID1_FIR_COEF_V_i	Configuration of the vertical scaling coefficients for the video pipeline 1
DISPC_VID2_FIR_COEF_V_i	Configuration of the vertical scaling coefficients for the video pipeline 2
DISPC_VID3_FIR_COEF_V_i	Configuration of the vertical scaling coefficients for the video pipeline 3

Table 10-105. DISPC_VIDp_FIR_COEF_H2_i Logical Register Mapping

Hardware Register	Description
DISPC_VID1_FIR_COEF_H2_i	Configuration of the horizontal Cb and Cr scaling coefficients for the video pipeline 1
DISPC_VID2_FIR_COEF_H2_i	Configuration of the horizontal Cb and Cr scaling coefficients for the video pipeline 2
DISPC_VID3_FIR_COEF_H2_i	Configuration of the horizontal Cb and Cr scaling coefficients or the video pipeline 3

Table 10-106. DISPC_VIDp_FIR_COEF_HV2_i Logical Register Mapping

Hardware Register	Description
DISPC_VID1_FIR_COEF_HV2_i	Configuration of the horizontal Cb and Cr scaling coefficients for the video pipeline 1
DISPC_VID2_FIR_COEF_HV2_i	Configuration of the horizontal Cb and Cr scaling coefficients for the video pipeline 2
DISPC_VID3_FIR_COEF_HV2_i	Configuration of the horizontal Cb and Cr scaling coefficients for the video pipeline 3

Table 10-107. DISPC_VIDp_FIR_COEF_V2_i Logical Register Mapping

Hardware Register	Description
DISPC_VID1_FIR_COEF_V2_i	Configuration of the vertical Cb and Cr scaling coefficients for the video pipeline 1
DISPC_VID2_FIR_COEF_V2_i	Configuration of the vertical Cb and Cr scaling coefficients for the video pipeline 2
DISPC_VID3_FIR_COEF_V2_i	Configuration of the vertical Cb and Cr scaling coefficients for the video pipeline 3

Table 10-108. DISPC_VIDp_CONV_COEF0 Logical Register Mapping

Hardware Register	Description
DISPC_VID1_CONV_COEF0	Configuration of the Color Space Conversion coefficients for the video pipeline 1
DISPC_VID2_CONV_COEF0	Configuration of the Color Space Conversion coefficient for the video pipeline 2

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 10-108. DISPC_VIDp_CONV_COEF0 Logical Register Mapping (continued)

Hardware Register	Description
DISPC_VID3_CONV_COEF0	Configuration of the Color Space Conversion coefficient for the video pipeline 3

Table 10-109. DISPC_VIDp_CONV_COEF1 Logical Register Mapping

Hardware Register	Description
DISPC_VID1_CONV_COEF1	Configuration of the Color Space Conversion coefficients for the video pipeline 1
DISPC_VID2_CONV_COEF1	Configuration of the Color Space Conversion coefficient for the video pipeline 2
DISPC_VID3_CONV_COEF1	Configuration of the Color Space Conversion coefficient for the video pipeline 3

Table 10-110. DISPC_VIDp_CONV_COEF2 Logical Register Mapping

Hardware Register	Description
DISPC_VID1_CONV_COEF2	Configuration of the Color Space Conversion coefficients for the video pipeline 1
DISPC_VID2_CONV_COEF2	Configuration of the Color Space Conversion coefficient for the video pipeline 2
DISPC_VID3_CONV_COEF2	Configuration of the Color Space Conversion coefficient for the video pipeline 3

Table 10-111. DISPC_VIDp_CONV_COEF3 Logical Register Mapping

Hardware Register	Description
DISPC_VID1_CONV_COEF3	Configuration of the Color Space Conversion coefficients for the video pipeline 1
DISPC_VID2_CONV_COEF3	Configuration of the Color Space Conversion coefficient for the video pipeline 2
DISPC_VID3_CONV_COEF3	Configuration of the Color Space Conversion coefficient for the video pipeline 3

Table 10-112. DISPC_VIDp_CONV_COEF4 Logical Register Mapping

Hardware Register	Description
DISPC_VID1_CONV_COEF4	Configuration of the Color Space Conversion coefficients for the video pipeline 1
DISPC_VID2_CONV_COEF4	Configuration of the Color Space Conversion coefficient for the video pipeline 2
DISPC_VID3_CONV_COEF4	Configuration of the Color Space Conversion coefficient for the video pipeline 3

Table 10-113. DISPC_CONTROLo Logical Register Mapping

Hardware Register	Description
DISPC_CONTROL1	Configuration control of the LCD1 and TV.
DISPC_CONTROL2	Configuration control of the LCD2.
DISPC_CONTROL3	Configuration control of the LCD3.

PRELIMINARY

Table 10-114. DISPC_CONFIGo Logical Register Mapping

Hardware Register	Description
DISPC_CONFIG1	Configuration of the LCD1 and TV.
DISPC_CONFIG2	Configuration of the LCD2.
DISPC_CONFIG3	Configuration of the LCD3.

Table 10-115. DISPC_DEFAULT_COLORo Logical Register Mapping

Hardware Register	Description
DISPC_DEFAULT_COLOR0	Configuration of the background color for LCD1.
DISPC_DEFAULT_COLOR1	Configuration of the background color for TV.
DISPC_DEFAULT_COLOR2	Configuration of the background color for LCD2.
DISPC_DEFAULT_COLOR3	Configuration of the background color for LCD3.

Table 10-116. DISPC_TRANS_COLORo Logical Register Mapping

Hardware Register	Description
DISPC_TRANS_COLOR0	Configuration of the transparency color key for LCD1.
DISPC_TRANS_COLOR1	Configuration of the transparency color key for TV.
DISPC_TRANS_COLOR2	Configuration of the transparency color key for LCD2.
DISPC_DEFAULT_COLOR3	Configuration of the background color for LCD3.

Table 10-117. DISPC_GAMMA_TABLEo Logical Register Mapping

Hardware Register	Description
DISPC_GAMMA_TABLE0	Configuration of the palette table for GFX or the gamma table for LCD1.
DISPC_GAMMA_TABLE1	Configuration of the gamma table for LCD2.
DISPC_GAMMA_TABLE2	Configuration of the gamma table for TV output.
DISPC_GAMMA_TABLE3	Configuration of the gamma table for LCD3.

Table 10-118. DISPC_TIMING_Ho Logical Register Mapping

Hardware Register	Description
DISPC_TIMING_H1	Configuration of the horizontal timing for LCD1.
DISPC_TIMING_H2	Configuration of the horizontal timing for LCD2.
DISPC_TIMING_H3	Configuration of the horizontal timing for LCD3.

Table 10-119. DISPC_TIMING_Vo Logical Register Mapping

Hardware Register	Description
DISPC_TIMING_V1	Configuration of the vertical timing for LCD1.
DISPC_TIMING_V2	Configuration of the vertical timing for LCD2.
DISPC_TIMING_V3	Configuration of the vertical timing for LCD3.

Table 10-120. DISPC_POL_FREQo Logical Register Mapping

Hardware Register	Description
DISPC_POL_FREQ1	Configuration of the output signals for LCD1.
DISPC_POL_FREQ2	Configuration of the output signals for LCD2.
DISPC_POL_FREQ3	Configuration of the output signals for LCD3.

PRELIMINARY

Table 10-121. DISPC_DIVISORo Logical Register Mapping

Hardware Register	Description
DISPC_DIVISOR1	Configuration of the divisors for LCD1.
DISPC_DIVISOR2	Configuration of the divisors for LCD2.
DISPC_DIVISOR3	Configuration of the divisors for LCD3.

Table 10-122. DISPC_SIZE_LCDo Logical Register Mapping

Hardware Register	Description
DISPC_SIZE_LCD1	Configuration of the divisors for LCD1.
DISPC_SIZE_LCD2	Configuration of the divisors for LCD2.
DISPC_SIZE_LCD3	Configuration of the divisors for LCD3.

Table 10-123. DISPC_SIZE Logical Register Mapping

Hardware Register	Description
DISPC_SIZE_LCD1	Configuration of the LCD size on LCD1.
DISPC_SIZE_LCD2	Configuration of the LCD size on LCD2.
DISPC_SIZE_LCD3	Configuration of the LCD size on LCD3.

Table 10-124. DISPC_DATAo_CYCLE1 Logical Register Mapping

Hardware Register	Description
DISPC_DATA1_CYCLE1	Configuration of the output data format for first cycle on LCD1.
DISPC_DATA2_CYCLE1	Configuration of the output data format for first cycle on LCD2.
DISPC_DATA3_CYCLE1	Configuration of the output data format for first cycle on LCD3.

Table 10-125. DISPC_DATAo_CYCLE2 Logical Register Mapping

Hardware Register	Description
DISPC_DATA1_CYCLE2	Configuration of the output data format for second cycle on LCD1.
DISPC_DATA2_CYCLE2	Configuration of the output data format for second cycle on LCD2.
DISPC_DATA3_CYCLE2	Configuration of the output data format forsecond cycle on LCD3.

Table 10-126. DISPC_DATAo_CYCLE3 Logical Register Mapping

Hardware Register	Description
DISPC_DATA1_CYCLE3	Configuration of the output data format for third cycle on LCD1.
DISPC_DATA2_CYCLE3	Configuration of the output data format for third cycle on LCD2.
DISPC_DATA3_CYCLE3	Configuration of the output data format for third cycle on LCD3.

Table 10-127. DISPC_CPRo_COEF_R Logical Register Mapping

Hardware Register	Description
DISPC_CPR1_COEF_R	Configuration of the CPR matrix coefficients for the red component on LCD1.
DISPC_CPR2_COEF_R	Configuration of the CPR matrix coefficients for the red component on LCD2.
DISPC_CPR3_COEF_R	Configuration of the CPR matrix coefficients for the red component on LCD3

PRELIMINARY

Table 10-128. DISPC_CPRo_COEF_G Logical Register Mapping

Hardware Register	Description
DISPC_CPR1_COEF_G	Configuration of the CPR matrix coefficients for the green component on LCD1.
DISPC_CPR2_COEF_G	Configuration of the CPR matrix coefficients for the green component on LCD2.
DISPC_CPR3_COEF_G	Configuration of the CPR matrix coefficients for the green component on LCD3.

Table 10-129. DISPC_CPRo_COEF_B Logical Register Mapping

Hardware Register	Description
DISPC_CPR1_COEF_B	Configuration of the CPR matrix coefficients for the blue component on LCD1.
DISPC_CPR2_COEF_B	Configuration of the CPR matrix coefficients for the blue component on LCD2.
DISPC_CPR3_COEF_B	Configuration of the CPR matrix coefficients for the blue component on LCD3.

10.2.7.3 DISPC Registers

10.2.7.3.1 DISPC Register Summary

Table 10-130. DISPC Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	L3_MAIN Physical Address

Table 10-133. DISPC_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x5800 1010	**Instance**	DISPC
Description	This register allows to control various parameters of the OCP interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																		MIDLEMODE		RESERVED		CLOCKACTIVITY		RESERVED		WARMRESET		SIDLEMODE		ENWAKEUP		SOFTRESET		AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:14	RESERVED	Write 0s for future compatibility. Reads returns 0.	R	0x00000
13:12	MIDLEMODE	Master interface power management, standby/wait control 0x0: Force-standby. MStandby is only asserted when the module is disabled. MStandby is only asserted when the module is disabled. 0x1: No-Standby: MStandby is never asserted. 0x2: Smart-Standby. MStandby is asserted based on the internal activity of the module. 0x3: Reserved	RW	0x0
11:10	RESERVED	Write 0s for future compatibility. Reads returns 0	R	0x0

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
9:8	CLOCKACTIVITY	Clocks activity during wake up mode period 0x0: OCP and functional clocks can be switched off. 0x1: Functional clocks can be switched off and OCP clocks are maintained during wake up period. 0x2: OCP clocks can be switched off and Functional clocks are maintained during wake up period. 0x3: OCP and functional clocks are maintained during wake-up period.	RW	0x0
7:6	RESERVED	Write 0s for future compatibility. Reads returns 0	R	0x0
5	WARMRESET	Warm reset. Set this bit to 1 triggers a module warm reset. The bit is automatically reset by the hardware. During reads, it always returns 0. The warm reset keep the configuration registers unchanged. 0x0: Normal mode 0x1: The warm reset is set.	RW	0
4:3	SIDLEMODE	Slave interface power management, Idle req/ack control 0x0: Force-idle. An idle request is acknowledged unconditionally. 0x1: No-idle. An idle request is never acknowledged. 0x2: Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module. 0x3: Reserved	RW	0x0
2	ENWAKEUP	WakeUp feature control 0x0: Wakeup is disabled. 0x1: Wakeup is enabled.	RW	0
1	SOFTRESET	Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset.	RW	0
0	AUTOIDLE	Internal interface clock gating strategy 0x0: Interface clock is free-running. 0x1: Automatic interface L3_MAIN gating strategy is applied, based on the OCP interface activity. Automatic functional clock gating is also applied to the functional clock based on the module activity (for instance DISPC_<pipe>_ATTRIBUTES.ENABLE).	RW	1

Bits	Field Name	Description	Type	Reset
31	FLIPIMMEDIATEDONE_IRQ	Flip Immediate Done. The DMA engine has acknowledged the immediate BA change, and software can write the new BA0. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
30	FRAMEDONE3_IRQ	Frame done for the third LCD. The third LCD output has been disabled by user. All the data have been sent. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
29	ACBIASCOUNT STATUS3_IRQ	AC bias count status for the third LCD 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
28	VSYNC3_IRQ	Vertical synchronization for the third LCD 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
27	SYNCLOST3_IRQ	Synchronization lost on the third LCD output. The required data are not output at the correct time due to too short blanking periods or stall of at least one pipelines associated with the third LCD output. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
26	WBUNCOMPLETE ERROR_IRQ	Write-back DMA buffer is flushed before it is completely drained. In WB capture mode, if the new frame starts before the WB DMA buffers are fully drained (onto external memory), then the contents of the WB DMA buffers are lost (implying last few pixels/lines are corrupted in the captured frame in memory). This interrupt is an indication of that case and will trigger every frame 0x0: READS: Event is false. WRITES: Status bit unchanged 0x1: READS: Event is true (Pending) WRITES: Status bit is reset	RW W1toClr	0
25	WBBUFFER OVERFLOW_IRQ	Write-back DMA buffer overflow. The DMA buffer is full. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
24	FRAME DONETV_IRQ	Frame done for the TV. The TV output has been disabled by user. All the data have been sent. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
23	FRAME DONEWB_IRQ	Frame done for the write-back channel. The write-back channel has output the frame. All the data of the frame have been sent to the memory. There is no pending data inside the DMA engine for the write-back channel to be transferred to memory. It is available only when the write-back pipeline transfers back to memory the output of one of the pipelines. In case of overlay capture, the interrupt is not generated and the user shall use the FrameDone for the corresponding captured output. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0

PRELIMINARY

Bits	Field Name	Description	Type	Reset
22	FRAME DONE2_IRQ	Frame done for the secondary LCD. The secondary LCD output has been disabled by user. All the data have been sent. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
21	ACBIASCOUNT STATUS2_IRQ	AC bias count status for the secondary LCD 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
20	VID3BUFFER UNDERFLOW_IRQ	Video 3 DMA buffer underflow. The DMA buffer is not necessarily empty but required data are not present in the DMA buffer (due to out of order responses) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
19	VID3END WINDOW_IRQ	The end of the video 3 window has been reached. It is detected by the overlay manager when the full video 3 has been displayed. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
18	VSYNC2_IRQ	Vertical synchronization for the secondary LCD 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
17	SYNC LOST2_IRQ	Synchronization lost on the secondary LCD output. The required data are not output at the correct time due to too short blanking periods or stall of at least one pipelines associated with the secondary LCD output. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
16	WAKEUP_IRQ	Wakeup 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
15	SYNCLOST TV_IRQ	Synchronization lost on the TV output. The required data are not output at the correct time due to too short blanking periods or stall of at least one pipelines associated with the TV output. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
14	SYNC LOST1_IRQ	Synchronizationl ost on the primary LCD output. The required data are not output at the correct time due to too short blanking periods or stall of at least one pipelines associated with the primary LCD output. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
13	VID2END WINDOW_IRQ	The end of the video 2 Window has been reached. It is detected by the overlay manager when the full video 2 has been displayed. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
12	VID2BUFFER UNDERFLOW_IRQ	Video 2 DMA buffer underflow. The DMA buffer is not necessarily empty but required data are not present in the DMA buffer (due to out of order responses) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
11	VID1END WINDOW_IRQ	The end of the video 1 Window has been reached. It is detected by the overlay manager when the full video 1 has been displayed. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
10	VID1BUFFER UNDERFLOW_IRQ	Video 1 DMA buffer underflow. The DMA buffer is not necessarily empty but required data are not present in the DMA buffer (due to out of order responses) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
9	OCPERROR_IRQ	OCP error. L3_MAIN Interconnect has sent SResp=ERR. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
8	PALETTEGAMMA LOADING_IRQ	Palette Gamma loading status. The palette used as Color Look Up Table (CLUT) for the graphics BITMAP formats (1-, 2-, 4-, or 4-bpp) or as gamma table for the overlay output for the primary LCD output has been loaded successfully. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
7	GFXEND WINDOW_IRQ	The end of the graphics wndow has been reached. It is detected by the overlay manager when the full graphics has been displayed. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
25	WBBUFFER OVERFLOW_EN	Write-back DMA buffer overflow. The DMA buffer is full. 0x0: WBBufferOverflow is masked. 0x1: WBBufferOverflow generates an interrupt when it occurs.	RW	0
24	FRAME DONETV_EN	Frame done for the TV. The TV output has been disabled by user. All the data have been sent. 0x0: Frame Done for the TV output is masked. 0x1: Frame Done for the TV output generates an interrupt when it occurs.	RW	0
23	FRAME DONEWB_EN	Frame done for the write-back channel. The write-back channel has output the frame. All the data have been sent for the frame have been sent to the memory. There is no pending data inside the DMA engine for the write-back channel to be transferred to memory. 0x0: Frame done for the write-back is masked. 0x1: Frame done for the write-back generates an interrupt when it occurs.	RW	0
22	FRAME DONE2_EN	Frame done for the secondary LCD. The secondary LCD output has been disabled by user. All the data have been sent. 0x0: Frame done for the secondary LCD is masked. 0x1: Frame done for the secondary LCD generates an interrupt when it occurs.	RW	0
21	ACBIASCOUNT STATUS2_EN	AC Bias count status for the secondary LCD 0x0: ACBiasCountStatus for the secondary LCD output is masked. 0x1: ACBiasCountStatus for the secondary LCD output generates an interrupt when it occurs.	RW	0
20	VID3BUFFER UNDERFLOW_EN	Video 3 DMA Buffer Underflow. The DMA buffer is not necessary empty but required data are not present in the DMA buffer (due to out of order responses) 0x0: Vid3BufferUnderflow is masked. 0x1: Vid3BufferUnderflow generates an interrupt when it occurs.	RW	0
19	VID3END WINDOW_EN	The end of the video 3 window has been reached. It is detected by the overlay manager when the full video 3 has been displayed. 0x0: Vid3EndWindow is masked. 0x1: Vid3EndWindow generates an interrupt when it occurs.	RW	0
18	VSYNC2_EN	Vertical synchronization for the secondary LCD 0x0: VSYNC for the secondary LCD output is masked. 0x1: VSYNC for the secondary LCD output generates an interrupt when it occurs.	RW	0
17	SYNC LOST2_EN	Synchronization lost on the secondary LCD output. The required data are not output at the correct time due to too short blanking periods or stall of at least one pipelines associated with the secondary LCD output. 0x0: Synchronization Lost on the secondary LCD output is masked. 0x1: Synchronization Lost on the secondary LCD output generates an interrupt when it occurs.	RW	0
16	WAKEUP_EN	Wake up mask 0x0: WakeUp is masked. 0x1: WakeUp generates an interrupt when it occurs.	RW	0

Bits	Field Name	Description	Type	Reset
15	SYNC LOSTTV_EN	Synchronization lost on the TV output. The required data are not output at the correct time due to too short blanking periods or stall of at least one pipelines associated with the TV output. 0x0: Synchronization Lost on the TV output is masked. 0x1: Synchronization Lost on the TV output generates an interrupt when it occurs.	RW	0
14	SYNC LOST1_EN	Synchronization lost for the primary LCD 0x0: SyncLost for the primary LCD output is masked. 0x1: SyncLost for the primary LCD output generates an interrupt when it occurs.	RW	0
13	VID2END WINDOW_EN	The end of the video 2 Window has been reached. It is detected by the overlay manager when the full video 2 has been displayed. 0x0: Vid2EndWindow is masked. 0x1: Vid2EndWindow generates an interrupt when it occurs.	RW	0
12	VID2BUFFER UNDERFLOW_EN	Video 2 DMA buffer underflow. The DMA buffer is not necessary empty but required data are not present in the DMA buffer (due to out of order responses) 0x0: Vid2BufferUnderflow is masked. 0x1: Vid2BufferUnderflow generates an interrupt when it occurs.	RW	0
11	ENDVID1 WINDOW_EN	The end of the video 1 window has been reached. It is detected by the overlay manager when the full video 1 has been displayed. 0x0: EndVid1Window is masked. 0x1: EndVid1Window generates an interrupt when it occurs.	RW	0
10	VID1BUFFER UNDERFLOW_EN	Video 1 DMA buffer underflow. The DMA buffer is not necessary empty but required data are not present in the DMA buffer (due to out of order responses) 0x0: Vid1bufferunderflow is masked. 0x1: Vid1bufferunderflow generates an interrupt when it occurs.	RW	0
9	OCPERROR_EN	OCP Error. L3_MAIN Interconnect has sent SResp=ERR. 0x0: OCPError is masked. 0x1: OCPError generates an interrupt when it occurs.	RW	0
8	PALETTE GAMMA_EN	Palette gamma loading mask. The palette used as Color Look Up Table (CLUT) for the graphics BITMAP formats (1-, 2-, 4-, or 4-bpp) or as gamma table for the overlay output for the primary LCD output has been loaded successfully. 0x0: PaletteGamma is masked. 0x1: PaletteGamma generates an interrupt when it occurs.	RW	0
7	GFXEND WINDOW_EN	The end of the graphics Window has been reached. It is detected by the overlay manager when the full graphics has been displayed. 0x0: GfxEndWindow is masked. 0x1: GfxEndWindow generates an interrupt when it occurs.	RW	0
6	GFXBUFFER UNDERFLOW_EN	Graphics DMA Buffer Underflow. The DMA buffer is not necessarily empty but required data are not present in the DMA buffer (due to out of order responses) 0x0: GfxBufferUnderflow is masked. 0x1: GfxBufferUnderflow generates an interrupt when it occurs.	RW	0

Bits	Field Name	Description	Type	Reset
5	PROGRAMMED LINENUMBER_EN	Programmed Line Number. It indicates that the scan of the primary LCD has reached the programmed user line number. 0x0: ProgrammedLineNumber is masked. 0x1: ProgrammedLineNumber generates an interrupt when it occurs.	RW	0
4	ACBIASCOUNT STATUS1_EN	AC Bias count status for the primary LCD 0x0: ACBiascountstatus for the primary LCD output is masked. 0x1: ACBiascountstatus for the primary LCD output generates an interrupt when it occurs.	RW	0
3	EVSYNC_ODD_EN	VSYNC for odd field from the TV encoder (HDMI) 0x0: EVSYNC_ODD for the TV output is masked. 0x1: EVSYNC_ODD for the TV output generates an interrupt when it occurs.	RW	0
2	EVSYNC_EVEN_EN	VSYNC for even field from the TV encoder (HDMI) 0x0: EVSYNC_EVEN for the TV output is masked. 0x1: EVSYNC_EVEN for the TV output generates an interrupt when it occurs.	RW	0
1	VSYNC1_EN	Vertical synchronization for the primary LCD. 0x0: VSYNC for the primary LCD output is masked. 0x1: VSYNC for the primary LCD output generates an interrupt when it occurs.	RW	0
0	FRAMEDONE_EN	Frame done for the primary LCD. The primary LCD output has been disabled by user. All the data have been sent. 0x0: Frame Done for the primary LCD output is masked. 0x1: FrameDone for the primary LCD output generates an interrupt when it occurs.	RW	0

Table 10-143. DISPC_CONFIG1

Address Offset	0x0000 0044		
Physical Address	0x5800 1044	**Instance**	DISPC
Description	The control register configures the Display Controller module for the primary LCD output and TV output. Shadow register, updated on VFP start period of primary LCD or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory

Bits	Field Name	Description	Type	Reset
22	OUTPUTMODE ENABLE	Selects between progressive and interlace mode for the primary LCD output. wr: VFP start of primary LCD 0x0: Progressive mode selected. 0x1: Interlace mode selected.	RW	0
21:20	RESERVED	Write 0s for future compatibility. Reads return 0.	RW	0
19	TVALPHABLENDER ENABLE	Selects the alpha blender overlay manager for the TV output instead of the color key alpha blender (LCD output). The bit field is deprecated. It is present for software backward compatibility only. When it is enabled, the Z-order defined in each ATTRIBUTES registers for only the pipelines associated pipeline connected to the TV output are invalid and replaced by the following: graphics z-order = 3, video3 z-order = 2, video2 z-order =1 and video1 z-order=0 If it disabled, the z-order and z-order enable bit fields defined in each ATTRIBUTES register are used. wr: EVSYNC start of primary LCD 0x0: Alpha blender is disabled. 0x1: The alpha blender is enabled.	RW	0
18	LCDALPHABLENDER ENABLE	Selects the alpha blender overlay manager for the primary LCD output instead of the color key alpha blender (LCD output). The bit field is deprecated. It is present for software backward compatibility only. When it is enabled, the Z-order defined in each ATTRIBUTES registers for only the pipelines associated with the primary LCD output are invalid and replaced by the following: graphics z-order = 3, video3 z-order = 2, video2 z-order =1 and video1 z-order=0 If it disabled, the z-order and z-order enable bit fields defined in each ATTRIBUTES register are used. wr: VFP start of primary LCD 0x0: Alpha blender is disabled. The color key alpha blending is used. 0x1: The alpha blender is enabled.	RW	0
17	BUFFERFILLING	Controls if the DMA buffers are refilled only when the LOW threshold is reached or if all DMA buffers are refilled when at least one of them reaches the LOW threshold. wr: immediate 0x0: Each DMA buffer is refilled when it reaches LOW threshold. 0x1: All DMA buffers are refilled up to high threshold when at least one of them reaches the LOW threshold. (only active DMA buffers shall be considered and when reaching the end of the frame the DMA buffer goes to empty condition so no need to fill it again).	RW	0
16	BUFFERHAND CHECK	Controls the handcheck between DMA buffer and STALL signal in order to prevent from underflow. The bit shall be set to 0 when the module is not in STALL mode. (primary LCD output) wr: VFP start of primary LCD 0x0: Only the STALL signal (generated by RFBI, DSI1_A or DSI1_C depending on which IP uses the LCD output) is used regardless of the DMA buffer fullness information in order to provide data to the RFBI,DSI1_A or DS1_C module. 0x1: The STALL signal (generated by RFBI, DSI1_A or DSI1_C depending on which IP uses the LCD output) is used in combination with the DMA buffer fullness information in order to provide data to the RFBI, DSI1_A or DSI1_C module only when it does not generated buffer underflow.	RW	0

Bits	Field Name	Description	Type	Reset
15	CPR	Color phase rotation control (primary LCD output). It shall be reset when ColorConvEnable bit field is set to 1 wr: VFP start period of primary LCD output 0x0: Color Phase Rotation Disabled 0x1: Color Phase Rotation Enabled	RW	0
14	BUFFERMERGE	Buffer merge control wr: EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory or VFP When enabled, the DISPC_GLOBAL_BUFFER register is ignored. This bit must be set to zero when the write back channel is used. When DISPC_CONTROL2.GOWB is used BUFFERMERGE MUST be zero. When DISPC_CONTROL2.GOWB is used BUFFERMERGE MUST be zero. WR: immediate 0x0: DMA buffer merge disabled Each DMA buffer is dedicated to one pipeline. 0x1: DMA buffer merge enabled All the DMA buffers are merged into a single one to be used by the single active pipeline.	RW	0
13	TCKTV SELECTION	Transparency color key selection (TV output) wr: EVSYNC 0x0: Destination transparency color key selected 0x1: Source transparency color key selected	RW	0
12	TCKTVENABLE	Transparency color key enabled (TV output) WR: EVSYNC 0x0: Disable the transparency color key for the TV output 0x1: Enable the transparency color key for the TV output	RW	0
11	TCKLCD SELECTION	Transparency color key selection (primary LCD output) wr: VFP start period of primary LCD output 0x0: Destination transparency color key selected 0x1: Source transparency color key selected	RW	0
10	TCKLCDENABLE	Transparency color key enabled (primary LCD output) wr: VFP start period of primary LCD output 0x0: Disable the transparency color key for the LCD 0x1: Enable the transparency color key for the LCD	RW	0
9	GAMATABLE ENABLE	For backward compatibility, an enable bit has been added on the 2 additional gamma tables (secondary display and TV). Gamma table of LCD1 is always enabled. 0x0: Gamma table LCD2 and TV are bypassed 0x1: Gamma table LCD2 and TV are enabled	RW	0
8	ACBIASGATED	ACBias Gated Enabled (primary LCD output) wr: VFP start period of primary LCD output 0x0: AcBias gated disabled 0x1: AcBias gated enabled	RW	0
7	VSYNCGATED	VSYNC Gated Enabled (primary LCD output) wr: VFP start period of primary LCD output 0x0: VSYNC gated disabled 0x1: VSYNC gated enabled	RW	0
6	HSYNCGATED	HSYNC Gated Enabled (primary LCD output) wr: VFP start period of primary LCD output 0x0: HSYNC gated disabled 0x1: HSYNC gated enabled	RW	0

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
31:30	CHANNELOUT2	It is not used if CHANNELOUT is set to TV. Reserved when CHANNELOUT = 1 (should set to zero) wr: immediate 0x0: Primary LCD output selected. 0x1: Secondary LCD output selected. 0x2: Third LCD output selected. 0x3: Write-back output to the memory selected.	RW	0x0
29	BURSTTYPE	The type of burst can be INCR (incremental) or BLCK (2D block). The 2D block is required when the TILER is targeted by the DMA engine. (It does not apply to the palette loading OCP requests using INCR burst only) 0x0: INC burst type is used. 0x1: 2D block burst type is used.	RW	0
28	PREMULTIPLYALPHA	The field configures the DISPC GFX to process incoming data as premultiplied alpha data or non premultiplied alpha data. Default setting is non premultiplied alpha data. 0x0: Non premultiplyalpha data color component 0x1: Premultiplyalpha data color component	RW	0
27:26	ZORDER	Z-Order defining the priority of the layer compared to others when overlaying. It is software responsibility to ensure that each layer connected to the same overlay manager has a different z-order value. If bit 25 is set to 0, the ZORDER bit field is ignored and replaced by the value 0. 0x0: Z-order 0: layer above solid background color and below layer with higher Z-order values. 0x1: Z-order 1: layer above layer with z-order value of 0 and below layers with z-order values of 2 and 3 0x3: Z-order 3: layer above all the other layers 0x2: Z-order 2: layer above layers with z-order value of 0 and 1 and below layer with z-order value of 3	RW	0x0
25	ZORDERENABLE	Z-order Enable. The bit field ZORDER is only used when the Z-order is enabled. 0x0: Z-order disabled. The Z-order of the layer is 0. 0x1: Z-order enabled. The Z-order is defined by the bit field ZORDER (bits 26 and 27).	RW	0
24	ANTIFLICKER	Antiflicker filtering using a 3-tap filter with hardcoded coefficients (1/4, 1/2, 1/4) 0x0: Antiflicker disabled. 0x1: Antiflicker enabled.	RW	0
23:21	RESERVED	Write 0s for future compatibility. Reads return 0.	R	0x0
20:18	SUBSAMPLINGPATTERN	Subsampling pattern setting.	RW	0x0
17	SELFREFRESHAUTO	Automatic self-refresh mode 0x0: The transition from Selfrefresh disabled to enabled is controlled by software 0x1: The transition from Selfrefresh disabled to enabled is controlled only by hardware	RW	0
16	FORCE1DTILEDMODE	Force TILED regions access to 1D or 2D. 0x0: 2D accesses for tiled regions 0x1: 1D accesses for tiled regions	RW	0x0

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
15	SELFREFRESH	Enables the self refresh of the graphics window from its own DMA buffer. This bit should be set only after having set the GO bit of the channel and read back a zero in its field. 0x0: The graphics pipeline accesses the interconnect to fetch data from the system memory. 0x1: The graphics pipeline does not need anymore to fetch data from memory. Only the graphics DMA buffer is used. It takes effect after the frame has been loaded in the DMA buffer.	RW	0
14	ARBITRATION	Determines the priority of the graphics pipeline. When the graphics pipeline is one of the high priority pipelines. The arbitration wheel gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The graphics pipeline is one of the normal priority pipeline. 0x1: The graphics pipeline is one of the high priority pipeline.	RW	0
13:12	ROTATION	Graphics rotation flag 0x0: No rotation 0x1: Rotation by 90 degrees 0x3: Rotation by 270 degrees 0x2: Rotation by 180 degrees	RW	0x0
11	BUFPRELOAD	Graphics preload value 0x0: Hardware prefetches pixels up to the preload value defined in the preload register 0x1: Hardware prefetches pixels up to high threshold value	RW	0
10	FRAMEPACKINGMODE	Frame packing mode control. 0x0: Frame Packing mode is disabled 0x1: Nibble mode is enabled	RW	0x0
9	NIBBLEMODE	Graphics nibble mode (only for 1-, 2- and 4 bpp) 0x0: Nibble mode is disabled 0x1: Nibble mode is enabled	RW	0
8	CHANNELOUT	Graphics Channel Out configuration: LCD, WB or TV. wr: immediate 0x0: LCD output or WB to the memory selected. bit fields 31 and 30 defines the output associated (primary, secondary or write-back). 0x1: TV output selected	RW	0
7:6	BURSTSIZE	Graphics DMA burst size 0x0: 2 × 128-bit bursts 0x1: 4 × 128-bit bursts 0x3: Reserved 0x2: 8 × 128-bit bursts	RW	0x2
5	REPLICATIONENABLE	Graphics replication enabled: RGB . ARGB, and RGBA formats are converted into ARGB32-8888 using replication of the MSBs or 0s 0x0: Disable graphics replication logic. The conversion to ARGB32-8888 is done by adding 0s for the LSBs 0x1: Enable graphics replication logic. The conversion to ARGB32-8888 is done by duplicating the MSBs for the LSBs	RW	1

Bits	Field Name	Description	Type	Reset
28	PREMULTIPHYALPHA	The field configures the DISPC VID1 to process incoming data as premultiplied alpha data or non premultiplied alpha data. Default setting is non premultiplied alpha data. 0x0: Non premultiplyalpha data color component 0x1: Premultiplyalpha data color component	RW	0
27:26	ZORDER	Z-Order defining the priority of the layer compared to others when overlaying. It is software responsibility to ensure that each layer connected to the same overlay manager has a different z-order value. If bit 25 is set to 0, the ZORDER bit field is ignored and replaced by the value 0. 0x0: Z-order 0: layer above solid background color and below layer with higher Z-order values. 0x1: Z-order 1: layer above layer with z-order value of 0 and below layers with z-order values of 2 and 3 0x3: Z-order 3: layer above all the other layers 0x2: Z-order 2: layer above layers with z-order value of 0 and 1 and below layer with z-order value of 3	RW	0x0
25	ZORDERENABLE	Z-order Enable. The bit field ZORDER is only used when the Z-order is enabled. 0x0: Z-order disabled. The Z-order of the layer is 0. 0x1: Z-order enabled. The Z-order is defined by the bit field ZORDER (bits 26 and 27).	RW	0
24	SELFREFRESH	Enables the self refresh of the video window from its own DMA buffer only. 0x0: The video pipeline accesses the interconnect to fetch data from the system memory. 0x1: The video pipeline does not need anymore to fetch data from memory. Only the DMA buffer associated with the video1 is used. It takes effect after the frame has been loaded in the DMA buffer.	RW	0
23	ARBITRATION	Determines the priority of the video pipeline. The video pipeline is one of the high priority pipeline. The arbitration gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The video pipeline is one of the normal priority pipeline. 0x1: The video pipeline is one of the high priority pipeline.	RW	0
22	DOUBLESTRIDE	Determines if the stride for CbCr buffer is the 1x or 2x of the Y buffer stride. It is only used in case of YUV4:2:0. 0x0: The CbCr stride value is equal to the Y stride. 0x1: The CbCr stride value is double to the Y stride.	RW	0
21	VERTICALTAPS	Video vertical resize tap number. The vertical polyphase filter can be configured in 3-tap or 5-tap configuration. According to the number of taps, the maximum input picture width is double while using 3-tap compared to 5-tap. 0x0: 3 taps are used for the vertical filtering logic. The 2 other taps are not used. The associated bit fields for the 2 other taps coefficients do not need to be initialized. 0x1: 5 taps are used for the vertical filtering logic.	RW	0
20	FORCE1DTILEDMODE	Force TILED regions access to 1D or 2D. 0x0: 2D accesses for tiled regions 0x1: 1D accesses for tiled regions	RW	0

Description	The bank of registers configure the down/up/down-scaling coefficients for the vertical and horizontal resize of the video picture associated with the video window 1 for the phases from 0 to 7. It is used for ARGB and Y setting. Shadow register, updated on VFP start period of primary LCD or VFP start period of the secondary LCD or VFP start period of the third LCD or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory

BA																															

Bits	Field Name	Description	Type	Reset
31:0	BA	Video base address Base address of the video buffer (aligned on pixel size boundary except in case of RGB24 packed format, 4-pixel alignment is required; in case of YUV4:2:2, 2-pixel alignment is required, and YUV4:2:0, byte alignment is supported)). In case of YUV4:2:0 format, it indicates the base address of the Y buffer. When the TILER is addressed, the bits: [28:27] = 0x0 for 8-bit tiled [28:27] = 0x1 for 16-bit tiled [28:27] = 0x2 for 32-bit tiled [28:27] = 0x3 for page mode [31:29] = 0x0 for 0-degree view [31:29] = 0x1 for 180-degree view + mirroring [31:29] = 0x2 for 0-degree view + mirroring [31:29] = 0x3 for 180-degree view [31:29] = 0x4 for 270-degree view + mirroring [31:29] = 0x5 for 270-degree view [31:29] = 0x6 for 90-degree view [31:29] = 0x7 for 90-degree view + mirroring Otherwise the bits indicated the corresponding bit address to access the SDRAM. Bits	Field Name	Description	Type	Reset
31:30	CHANNELOUT2	It is not used if CHANNELOUT is set to TV. Reserved when CHANNELOUT = 1 (must be set to zero) wr: immediate 0x0: Primary LCD output selected. 0x1: Secondary LCD output selected. 0x2: Third LCD output selected. 0x3: Write-back output to the memory selected.	RW	0x0
29	BURSTTYPE	The type of burst can be INCR (incremental) or BLCK (2D block). The 2D block is required when the TILER is targeted by the DMA engine. 0x0: INC burst type is used. 0x1: 2D block burst type is used.	RW	0

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
28	PREMULTIPLYALPHA	The field configures the DISPC VID2 to process incoming data as premultiplied alpha data or non premultiplied alpha data. Default setting is non premultiplied alpha data. 0x0: Non premultiplyalpha data color component 0x1: Premultiplyalpha data color component	RW	0
27:26	ZORDER	Z-Order defining the priority of the layer compared to others when overlaying. It is software responsibility to ensure that each layer connected to the same overlay manager has a different z-order value. If bit 25 is set to 0, the ZORDER bit field is ignored and replaced by the value 0. 0x0: Z-order 0: layer above solid background color and below layer with higher Z-order values. 0x1: Z-order 1: layer above layer with z-order value of 0 and below layers with z-order values of 2 and 3 0x3: Z-order 3: layer above all the other layers 0x2: Z-order 2: layer above layers with z-order value of 0 and 1 and below layer with z-order value of 3	RW	0x0
25	ZORDERENABLE	Z-order Enable. The bit field ZORDER is only used when the Z-order is enabled. 0x0: Z-order disabled. The Z-order of the layer is 0. 0x1: Z-order enabled. The Z-order is defined by the bit field ZORDER (bits 26 and 27).	RW	0
24	SELFREFRESH	Enables the self refresh of the video window from its own DMA buffer only. 0x0: The video pipeline accesses the interconnect to fetch data from the system memory. 0x1: The video pipeline does not need anymore to fetch data from memory. Only the DMA buffer associated with the video2 is used. It takes effect after the frame has been loaded in the DMA buffer.	RW	0
23	ARBITRATION	Determines the priority of the video pipeline. The video pipeline is one of the high priority pipeline. The arbitration gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The video pipeline is one of the normal priority pipeline. 0x1: The video pipeline is one of the high priority pipeline.	RW	0
22	DOUBLESTRIDE	Determines if the stride for CbCr buffer is the 1x or 2x of the Y buffer stride. It is only used in case of YUV4:2:0. 0x0: The CbCr stride value is equal to the Y stride. 0x1: The CbCr stride value is double to the Y stride.	RW	0
21	VERTICALTAPS	Video Vertical Resize Tap Number 0x0: 3 taps are used for the vertical filtering logic. The 2 other taps are not used. The associated bit fields for the 2 other taps coefficients do not need to be initialized. 0x1: 5 taps are used for the vertical filtering logic.	RW	0
20	FORCE1DTILEDMODE	Force TILED regions access to 1D or 2D. 0x0: 2D accesses for tiled regions 0x1: 1D accesses for tiled regions	RW	0

PRELIMINARY

Table 10-237. DISPC_VID2_ROW_INC

Address Offset	0x0000 0168		
Physical Address	0x5800 1168	**Instance**	DISPC
Description	The register configures the number of bytes to increment at the end of the row for the buffer associated with the video window 2. Shadow register, updated on VFP start period of primary LCD or VFP start period of the secondary LCD or VFP start period of the third LCD or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ROWINC																															

Bits	Field Name	Description	Type	Reset
31:0	ROWINC	Number of bytes to increment at the end of the row Encoded signed value (from $2^{31}1$ to 2^{31}) to specify the number of bytes to increment at the end of the row in the video buffer. The value 0 is invalid. The value 1 means next pixel. The value 1 + n * bpp means increment of n pixels. The value 1 (n + 1) * bpp means decrement of n pixels.	RW	0x0000 0001

Table 10-239. DISPC_VID2_PIXEL_INC

Address Offset	0x0000 016C		
Physical Address	0x5800 116C	**Instance**	DISPC
Description	The register configures the number of bytes to increment between two pixels for the buffer associated with the video window 2. For more information, see Section 10.2.4.6.5, *Predecimation*.The register is used only when the TILER is not present in the system in order to perform low performance rotation. When the TILER IP is present it is highly recommended to use it for performing the rotation. Shadow register, updated on VFP start period of primary LCD or VFP start period of the secondary LCD or VFP start period of the third LCD or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory

Bits	Field Name	Description	Type	Reset
31:30	CHANNELOUT2	It is not used if CHANNELOUT is set to TV. Reserved when CHANNELOUT = 1 (should be set to zero) wr: immediate 0x0: Primary LCD output selected. 0x1: Secondary LCD output selected. 0x2: Third LCD output selected. 0x3: Write-back output to the memory selected.	RW	0x0
29	BURSTTYPE	The type of burst can be INCR (incremental) or BLCK (2D block). The 2D block is required when the TILER is targeted by the DMA engine. 0x0: INC burst type is used. 0x1: 2D block burst type is used.	RW	0
28	PREMULTIPLYALPHA	The field configures the DISPC VID3 to process incoming data as premultiplied alpha data or non premultiplied alpha data. Default setting is non premultiplied alpha data. 0x0: Non premultiplyalpha data color component 0x1: Premultiplyalpha data color component	RW	0

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
27:26	ZORDER	Z-Order defining the priority of the layer compared to others when overlaying. It is software responsibility to ensure that each layer connected to the same overlay manager has a different z-order value. If bit 25 is set to 0, the ZORDER bit field is ignored and replaced by the value 0. 0x0: Z-order 0: layer above solid background color and below layer with higher Z-order values. 0x1: Z-order 1: layer above layer with z-order value of 0 and below layers with z-order values of 2 and 3 0x3: Z-order 3: layer above all the other layers 0x2: Z-order 2: layer above layers with z-order value of 0 and 1 and below layer with z-order value of 3	RW	0x0
25	ZORDERENABLE	Z-order Enable. The bit field ZORDER is used only when the Z-order is enabled. 0x0: Z-order disabled. The Z-order of the layer is 0. 0x1: Z-order enabled. The Z-order is defined by the bit field ZORDER (bits 26 and 27).	RW	0
24	SELFREFRESH	Enables the self refresh of the video window from its own DMA buffer only. 0x0: The video pipeline accesses the interconnect to fetch data from the system memory. 0x1: The video pipeline does not need anymore to fetch data from memory. Only the DMA buffer associated with the video3 is used. It takes effect after the frame has been loaded in the DMA buffer.	RW	0
23	ARBITRATION	Determines the priority of the video pipeline. The video pipeline is one of the high priority pipeline. The arbitration gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The video pipeline is one of the normal priority pipeline. 0x1: The video pipeline is one of the high priority pipeline.	RW	0
22	DOUBLESTRIDE	Determines if the stride for CbCr buffer is the 1x or 2x of the Y buffer stride. It is only used in case of YUV4:2:0. 0x0: The CbCr stride value is equal to the Y stride. 0x1: The CbCr stride value is double to the Y stride.	RW	0
21	VERTICALTAPS	Video vertical resize tap number 0x0: 3 taps are used for the vertical filtering logic. The 2 other taps are not used. The associated bit fields for the 2 other taps coefficients do not need to be initialized. 0x1: 5 taps are used for the vertical filtering logic.	RW	0
20	FORCE1DTILEDMODE	Force TILED regions access to 1D or 2D. 0x0: 2D accesses for tiled regions 0x1: 1D accesses for tiled regions	RW	0
19	BUFPRELOAD	Video Preload Value 0x0: Hardware prefetches pixels up to the preload value defined in the preload register 0x1: Hardware prefetches pixels up to high threshold value	RW	0
18	RESERVED	Write 0s for future compatibility. Reads return 0.	R	0

Table 10-323. DISPC_VID3_PIXEL_INC

Address Offset	0x0000 0398		
Physical Address	0x5800 1398	**Instance**	DISPC
Description	The register configures the number of bytes to increment between two pixels for the buffer associated with the video window 3. For more information, see Section 10.2.4.6.5, *Predecimation*.The register is used only when the TILER is not present in the system in order to perform low performance rotation. When the TILER IP is present it is highly recommended to use it for performing the rotation. Shadow register, updated on VFP start period of primary LCD or VFP start period of the secondary LCD or VFP start period of the third LCD or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). Bits	Field Name	Description	Type	Reset
31:28	IDLENUMBER	Determines the number of idles between requests on the L3_MAIN interconnect. It is only used when the write-back pipeline does data transfer from memory to memory. When the output of an overlay is stored in memory through the write-back pipeline in capture mode, the bit field IDLENUMBER is ignored since a timing generator is used to time the transfer. The number of IDLE cycles is IDLENUMBER (from 0 to 15) if IDLESIZE = 0. The number of IDLE cycles is IDLENUMBERx8 (from 0 to 120) if IDLESIZE = 1 and BURSTSIZE = 2. The number of IDLE cycles is IDLENUMBERx4 (from 0 to 60) if IDLESIZE = 1 and BURSTSIZE = 1. The number of IDLE cycles is IDLENUMBERx2 (from 0 to 30) if IDLESIZE = 1 and BURSTSIZE = 0.	RW	0x0
27	IDLESIZE	Determines if the IDLENUMBER corresponds to a number of bursts or singles. 0x0: The number of idles between requests is defined by IDLENUMBER as number of cycles. 0x1: The number of idles between requests is defined by IDLENUMBER multiplied by burst size as number of cycles.	RW	0
26:24	CAPTUREMODE	Defines the frame rate capture. 0x6: Only one out of six frames is captured. The first one is captured then the second one is skipped and so on. 0x1: Only one frame is captured. 0x7: Only one out of seven frames is captured. The first one is captured then the second one is skipped and so on. 0x0: All frames are captures until the write-back channel is disabled or there is no more data generated by the overlay or the pipeline attached to the write-back channel. 0x2: Only one out of two frames is captured. The first one is captured, and then the second one is skipped, and so on. 0x4: Only one out of four frames is captured. The first one is captured, and then the second one is skipped, and so on. 0x5: Only one out of five frames is captured. The first one is captured, and then the second one is skipped, and so on. 0x3: Only one out of three frames is captured. The first one is captured, and then the second one is skipped, and so on.	RW	0x0
23	ARBITRATION	Determines the priority of the write-back pipeline. The write-back pipeline is one of the high priority pipeline. The arbitration gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The write-back pipeline is one of the normal priority pipeline. 0x1: The write-back pipeline is one of the high priority pipeline.	RW	0
22	DOUBLESTRIDE	Determines if the stride for CbCr buffer is the 1x or 2x of the Y buffer stride. It is only used in case of YUV4:2:0. 0x0: The CbCr stride value is equal to the Y stride. 0x1: The CbCr stride value is double to the Y stride.	RW	0

Bits	Field Name	Description	Type	Reset
21	VERTICALTAPS	Video Vertical Resize Tap Number 0x0: 3 taps are used for the vertical filtering logic. The 2 other taps are not used. 0x1: 5 taps are used for the vertical filtering logic.	RW	0
20	FORCE1DTILEDMODE	Force TILED regions access to 1D or 2D. 0x0: 2D accesses for tiled regions 0x1: 1D accesses for tiled regions	RW	0x0
19	WRITEBACKMODE	When connected to the overlay output of a channel the write back can operate as a simple transfer from memory to memory (composition engine) or as a capture channel. 0x0: Capture mode (default mode) 0x1: Memory-to-memory mode	RW	0x0
18:16	CHANNELIN	Video Channel In configuration WR: immediate 0x6: Video3 pipeline output 0x1: Secondary LCD output 0x0: Primary LCD overlay output 0x2: TV overlay output 0x4: Video1 pipeline output 0x5: Video2 pipeline output 0x3: Graphics pipeline output 0x7: Third LCD output	RW	0x0
15:14	BURSTSIZE	Write-back DMA Burst Size 0x0: 2 × 128-bit bursts 0x1: 4 × 128-bit bursts 0x3: Reserved 0x2: 8 × 128-bit bursts	RW	0x2
13:12	RESERVED	Reserved	RW	0x0
11	FULLRANGE	Color Space Conversion full range setting. 0x0: Limited range selected: 16 subtracted from Y before color space conversion 0x1: Full range selected: Y is not modified before the color space conversion	RW	0
10	TRUNCATIONENABLE	It applies only when the input format to the write-back pipeline from the overlay or directly from one of the pipelines is ARGB32. If the format is one of the YUV supported formats, the bit field is ignored. 0x0: Disable truncation logic 0x1: Enable truncation logic from ARGB32 to the pixel format defined in the field FORMAT.	RW	0
9	COLORCONVENABLE	Enable the color space conversion. The hardware does not enable/disable the conversion based on the pixel format. The bit field shall be reset when the format is not YUV. 0x0: Disable Color Space Conversion RGB to YUV 0x1: Enable Color Space Conversion RGB to YUV	RW	0
8	BURSTTYPE	The type of burst can be INCR (incremental) or BLCK (2D block). The 2D block is required when the TILER is targeted by the DMA engine. 0x0: INC burst type is used. 0x1: 2D block burst type is used.	RW	0

Table 10-393. DISPC_WB_SIZE

Address Offset	0x0000 05A8
Physical Address	0x5800 15A8 **Instance** DISPC
Description	The register configures the size of the output of overlay connected to the write-back pipeline when the overlay output is only used by the write-back pipeline. When the overlay is output on the primary LCD or secondary LCD or TV outputs, the size of the frame is defined in the DISPC_SIZE_LCD1, DISPC_SIZE_LCD2, and DISPC_SIZE_TV respectively. Shadow register, updated when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline) when the WB pipeline is directly connected to one of the pipelines (graphics or video), otherwise updated on VFP start period of primary LCD or VFP start period of secondary LCD or VFP start period of the third LCD or EVSYNC depending on which overlay output is selected as an input to the WB pipeline

Table 10-417. DISPC_VID1_FIR2

Address Offset	0x0000 063C		
Physical Address	0x5800 163C	**Instance**	DISPC
Description	The register configures the resize factors for horizontal and vertical up/downsampling of the video window 1. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the hardware, any value can be used for the bit fields. Shadow register, updated on VFP start period of primary LCD or VFP start period of the secondary LCD or VFP start period of the third LCD or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory		
Type	RW

Description	The register configures the resize factors for horizontal and vertical up/downsampling of the video window 3. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the hardware, any value can be used for the bit fields. Shadow register, updated on VFP start period of primary LCD or VFP start period of the secondary LCD or VFP start period of the third LCD or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory

10.3 MIPI Display Serial Interface

This section describes the MIPI® display serial interface (DSI) module for the device.

NOTE: This section contains information that is Copyright © 2005-2008 MIPI Alliance, Inc. All rights reserved.

MIPI Alliance Member Confidential.

All rights reserved. This material is reprinted with the permission of the MIPI Alliance, Inc. No part(s) of this document may be disclosed, reproduced or used for any purpose other than as needed to support the use of the products of TI.

See OMAP5430 MIPI Disclaimer for details.

10.3.1 DSI Overview

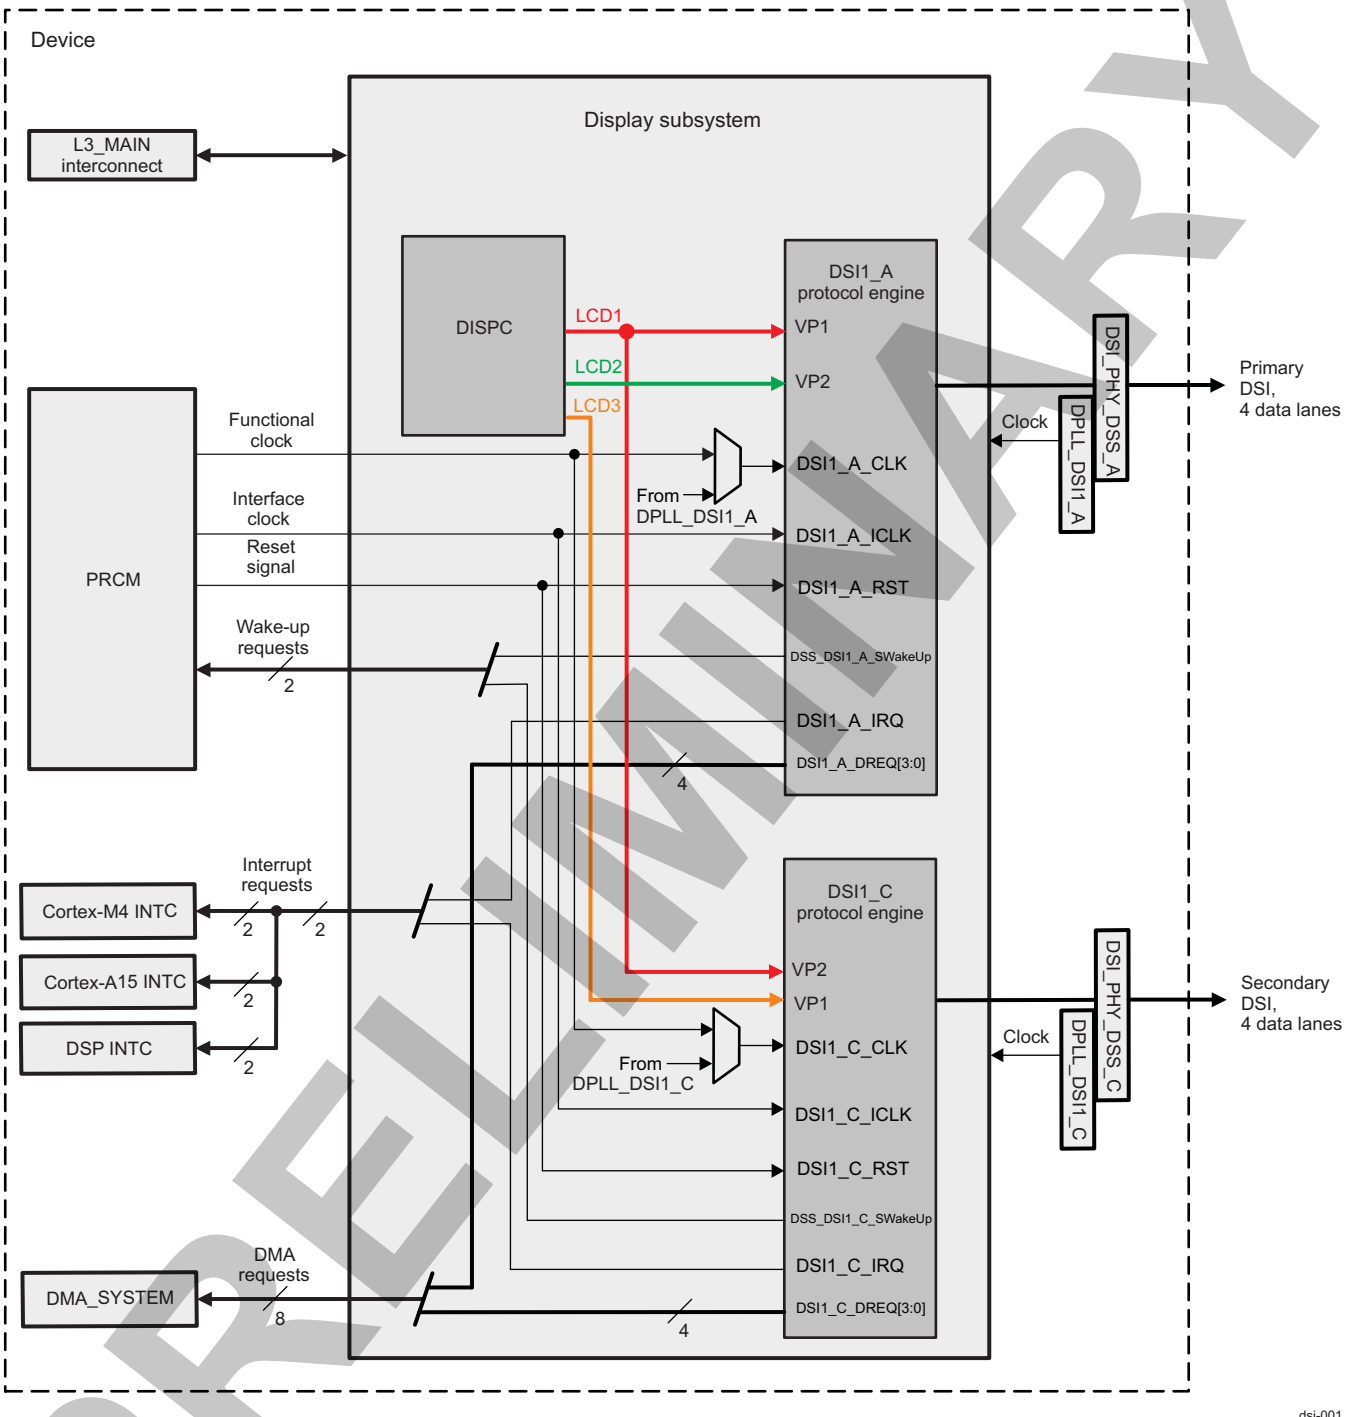
The DSI module connects to a DSI display module directly or through an external DSI bridge. The DSI module is connected to DISPC and L3_MAIN interconnect.

Figure 10-92 is a block diagram of the DSI module.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-92. DSI Overview



PRELIMINARY

Two DSI modules in the display subsystem provide the following main features:

- MIPI-DSI support (up to four data lanes and one clock lane)
- Video mode and command mode support
- Multiple display (one video mode and one command mode) support. In command mode, pixel data are provided from the level 3 (L3_MAIN) interface or from one of the overlay manager outputs.
- Bidirectional data link support for command mode (only one data lane is used in reverse direction)
- RGB16, RGB18 nonpacked, and RGB24 format support for command mode

Copyright © 2013, Texas Instruments Incorporated

- RGB16, RGB18 packed and nonpacked, and RGB24 format support for video mode
- Burst support for video mode
- Up to four data-configurable lane support, in addition to clock signaling
- Maximum data rate of 1256 Mbps per data pair for four-data lane configuration (627.75MHz at OPP_NOM.)
- Data splitter for 2-, 3-, and 4-data lane configurations
- Data interleaving support for one synchronous stream (video mode) from the DISPC and up to three asynchronous streams (command mode) from the interconnect concurrently, or up to four asynchronous streams (command mode) from the interconnect
- Transfer of pixels and data received on the video port or L3_MAIN interconnect to the display through DSI_PHY_DSS_x
- Serial configuration port (SCP) for the DSI_PHY_DSS_x complex input/output (I/O) and DSI phase-locked loop (PLL)
- Connection to the DSI_PHY_DSS_x DSI PHY through PPI (*MIPI D-PHY Specification v1.01.00 Revision 0.02 compliant*)
- Error-correction code (ECC) and checksum generation
- MIPI DCS support

PRELIMINARY

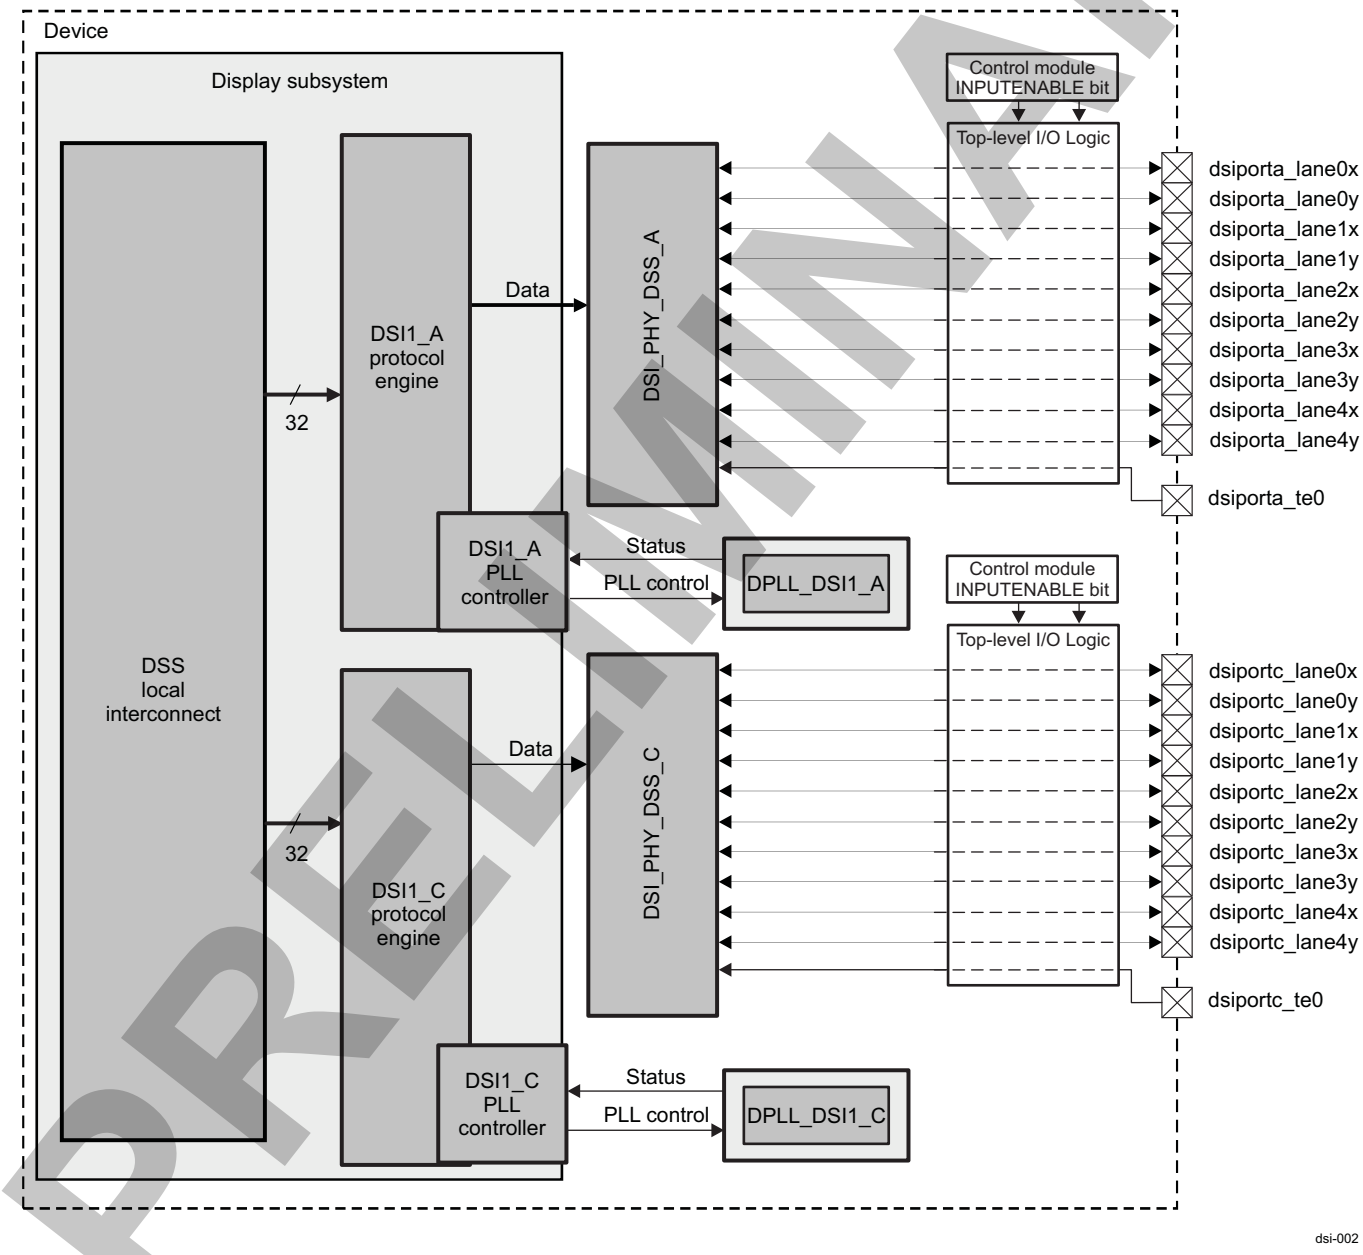
10.3.2 DSI Environment

NOTE: Copyright 2005-2008 MIPI Alliance, Inc. All rights reserved. MIPI Alliance Member Confidential.

This section describes the DSI application fields from an environment point of view (external connections). It describes the DSI connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

Figure 10-93 is a block diagram of the DSI environment.

Figure 10-93. DSI Environment



PRELIMINARY

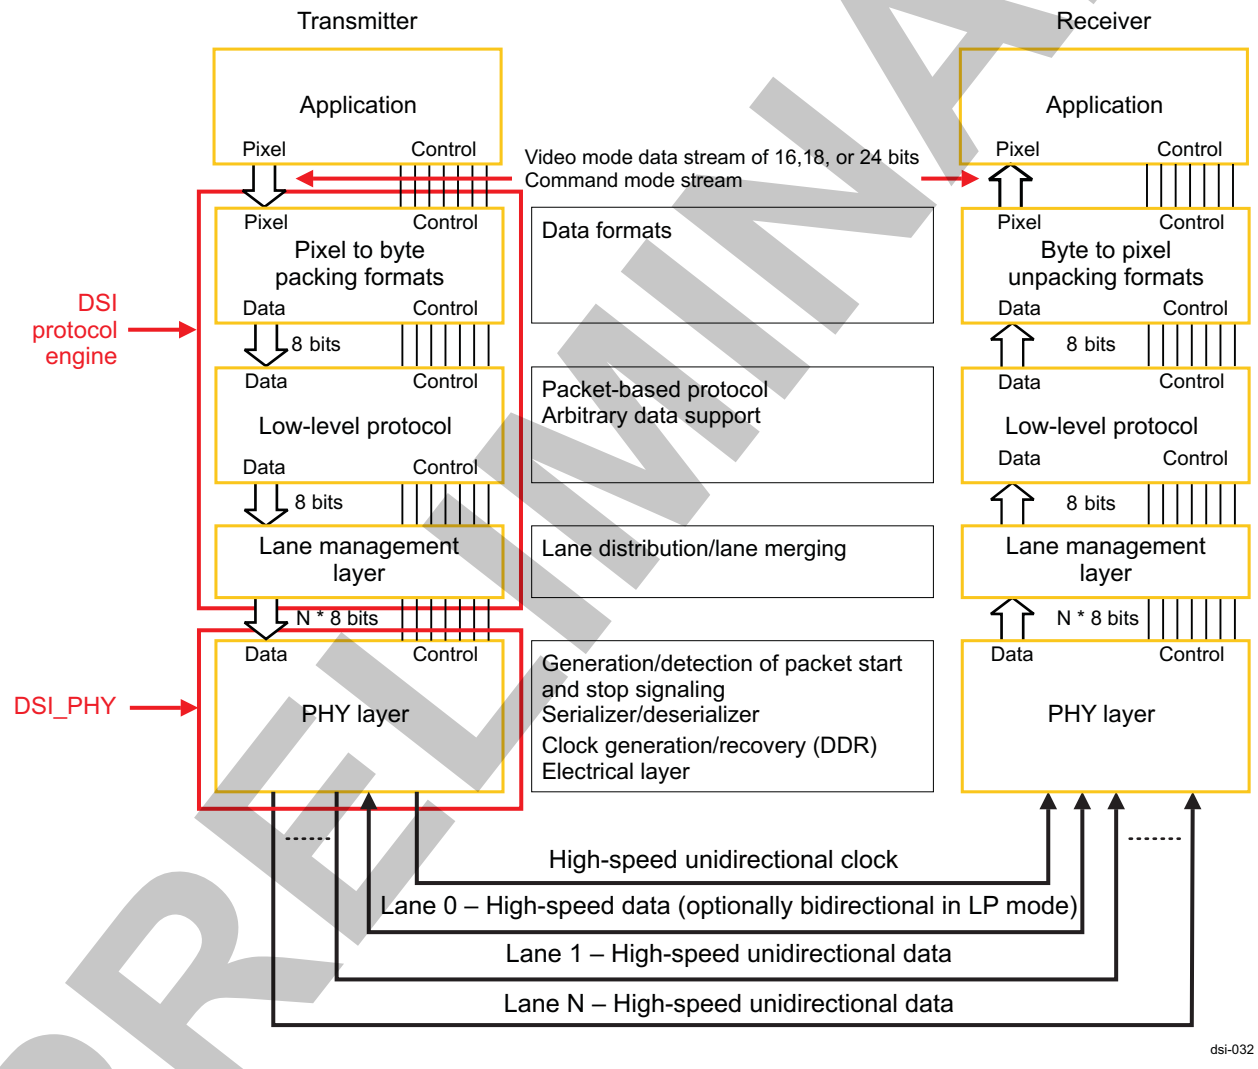
Copyright © 2013, Texas Instruments Incorporated

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the control module registers and dedicated IP registers. For more information, see , *Pad Functional Multiplexing and Configuration*, and , *Device Interfaces Signal Group Controls Mapping*, in Chapter 18, *Control Module*.

The DSI is a bidirectional differential serial interface with data/clock for the PHY (configured in unidirectional link in case the display module is only unidirectional). The maximum capacity of a DSI data transfer is 1255.5 Mbps for four data lanes. The speed of the link can be configured by software only when the DSI_PHY_DSS_x is in STOP state or ultralow-power state (ULPS).

Figure 10-94 shows the high-level data flow of the DSI transmitter/receiver.

Figure 10-94. DSI Transmitter/Receiver Data Flow



10.3.2.1 DSI PHY

Table 10-509 lists the DSI1_A and DSI1_C I/Os.

Table 10-509. DSI I/O Description of DSI1_A and DSI1_C

Signal Name		I/O[1]	Description	Value at Reset
dsi1portx_dx0	first lane	I/O	Serial data/clock lane	N/A

(1) I = Input; O = Output; I/O = Bidirectional

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

Table 10-509. DSI I/O Description of DSI1_A and DSI1_C (continued)

Signal Name		I/O[1]	Description	Value at Reset
dsi1portx_dy0				
dsi1portx_dx1 dsi1portx_dy1	second lane	I/O	Serial data/clock lane	N/A
dsi1portx_dx2 dsi1portx_dy2	third lane	I/O	Serial data/clock lane	N/A
dsi1portx_dx3 dsi1portx_dy3	fourth lane	I/O	Serial data/clock lane	N/A
dsi1portx_dx4 dsi1portx_dy4	fifth lane	I/O	Serial data lane only	N/A
dsi1portx_te0	te0	I	DSI1 tearing effect (TE) input 0	N/A

NOTE: Each serial lane can be used as a data lane. The first through fourth can be used as clock lanes (the fifth lane can never be the clock lane). All polarities on all lanes are supported. The MIPI DSI 1.01 protocol requires at least one clock lane and one data lane.

Lanes support four operating modes:

- HS mode: High-speed transmit mode
- LP mode: Low-power transmit mode (also called low-power state [LPS])
- ULPS: Ultralow-power state used between two transmissions
- Off mode: Lane is off.

NOTE: The CONTROL_DSIPHY register in the control module of the device provides the following control over the DSI lanes:

- Enable and disable each lane (the CONTROL_DSIPHY[28:24] DSIPORTA_LANEENABLE and CONTROL_DSIPHY[23:19] DSIPORTC_LANEENABLE bit fields).

For more information, see SYSCTRL_PADCONF_CORE Register Summary, in *Control Module*.

10.3.2.1.1 DSI Data/Clock Configuration

Data-clock signaling consists of one to four data pairs and one clock pair. The minimum configuration is one data pair and one clock pair.

- The data signal carries the bit serial data. The DSI transmitter in the host sends the data in-quadrature with the dual data rate (DDR) clock in HS mode; otherwise, the clock is extracted from the received data in LS mode. The data is transmitted byte-wise least-significant bit (LSB) first.
- The clock signal carries the DDR clock signal in HS transmission.
- Software users must configure the order of the data lanes to indicate the byte order while splitting the byte stream for each DSI_PHY_DSS_x into bytes.

Table 10-510 lists some of the DSI lane configurations.

NOTE: All combinations for the order of the clock and data lanes are supported (except clock cannot be on lane 5) but not explicitly described in Table 10-510.

NOTE:

- The byte on Dn is sent before the byte on Dn + 1; all combinations of data and clock are supported through programming of the DSI_COMPLEXIO_CFG1 register. The CLOCK_POSITION and CLOCK_POL bit fields configure which lane transmits the clock and define its polarity. Eight bit fields (DATA1_POSITION and DATA1_POL, through DATA4_POSITION and DATA4_POL) configure the data lanes and their polarity. The DATA2_POSITION through DATA4_POSITION bit fields can be set to 0; in this case, only the data lane defined in the DATA1_POSITION bit field is used, and data is transmitted on only one clock lane and one data lane.
- Only DATA1 is bidirectional in command mode. The low-power received information is always sent by the display panel using DATA1. Because any lane of DSI_PHY_DSS_x can be configured as data lane DATA1, all lanes of the PHY are bidirectional.

10.3.2.1.2 DSI ULPS

Each lane can be put in ULPS by software configuration. ULPS requires the following conditions:

- The lane must be in ULPS.
- For data lanes, no data must be pending in the DSI module.
- For the first data lane, no bus turnaround (BTA) should have been sent. The DSI module must have control of the bus.

For more information about ULPS configuration, see Section 10.3.4.4.16, *DSI ULPS Configuration*.

10.3.2.2 DSI Protocol Layer

Low-level protocol (LLP) is a byte-oriented protocol. It supports short and long packet formats. The DSI protocol layer defines how the display data is transported onto the PHY. Packets can be sent using HS mode or low-speed (LS) mode. LLP is selected through DSI registers. The DSI protocol layer features are:

- Transport of arbitrary data (payload independent)
- 8-bit word size
- Support for up to four interleaved VCs on the same link
- Special packets for frame start, frame end, line start, and line end information
- Descriptor for the type, pixel depth, and format of application-specific payload data
- ECC for 1-bit or 2-bit error detection in the header
- 16-bit checksum code for error detection

Figure 10-95 shows the protocol layer with short and long packets.

Figure 10-95. DSI Protocol Layer With Short and Long Packets

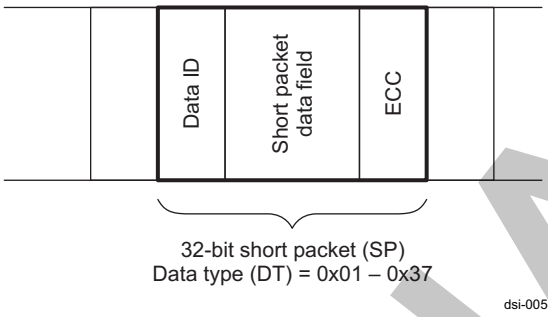
10.3.2.2.1 DSI Short Packet

Figure 10-96 shows the structure of the short packet. A short packet must contain an 8-bit data ID followed by two command or data bytes and an 8-bit ECC. No packet footer (PF) should be present. Short packets must be 4 bytes long. The ECC byte allows correction of single-bit errors and detection of 2-bit errors in the short packet.

Figure 10-96. DSI Short Packet Structure



NOTE: The short packets can be sent in LP mode or HS mode.

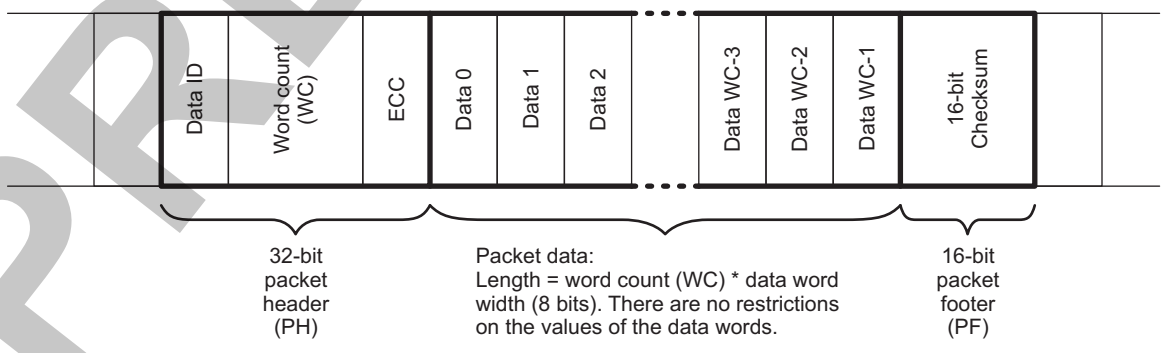
The DSI_VC_SHORT_PACKET_HEADER_i register is used to send only short packets (ECC can be calculated by hardware or by software users for debug purposes). This register is not used for video mode data because the short packets are generated by hardware based on the following events:

- Synchronization events received on the video port (assertion/deassertion of the HSYNC and VSYNC input signals)
- DSI_CTRL[18] VP_HSYNC_END
- DSI_CTRL[17] VP_HSYNC_START
- DSI_CTRL[16] VP_VSYNC_END
- DSI_CTRL[15] VP_VSYNC_START
- DSI_CTRL[11] VP_VSYNC_POL
- DSI_CTRL[10] VP_HSYNC_POL
- DSI_VC_CTRL_i[1] SOURCE

10.3.2.2.2 DSI Long Packet

Figure 10-97 shows the structure of the long packet. A long packet must consist of three elements: 32-bit packet header (PH), application-specific data payload with a variable number of bytes, and 16-bit PF.

Figure 10-97. DSI Long Packet Structure



The PH is further composed as follows:

- 8-bit data identifier: The data identifier defines the VC for the data and the DT for the application-

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

specific payload data.

- 16-bit word count: The word count defines the number of bytes in the data payload between the end of the PH and the start of the PF. The PH and the PF must not be included in the word count.
- 8-bit ECC: The ECC byte allows single-bit errors to be corrected and 2-bit errors to be detected in the PH. This includes the data identifier and the word count fields.

After the end of the PH, the receiver reads the next word count × bytes of the data payload. There are no limitations on the value of a data word within the data payload block (that is, no embedded codes are used). Once the receiver has read the data payload, it reads the checksum in the PF. The host processor must always calculate and transmit a checksum in the PF. Peripherals are not required to calculate a checksum. In the special case of a 0-byte data payload, if the payload length is 0, the checksum calculation results in (0xFFFF). If the checksum is not calculated, the PF must consist of 2 bytes of 0s (0x0000). In the generic case, the length of the data payload must be a multiple of bytes. In addition, each data format can impose additional restrictions on the length of the payload data (that is, a multiple of 4 bytes). Each byte is transmitted LSB first. Payload data can be transmitted in any byte order, restricted only by data format requirements. Multibyte elements, such as word count and checksum, must be transmitted least-significant byte (LSByte) first.

NOTE: Long packets can be sent in LP or HS mode.

The DSI_VC_LONG_PACKET_HEADER_i register provides headers for long packets (ECC is always calculated by hardware). The register is used for video and command modes.

If video mode is enabled for a virtual channel, it is not possible to transfer data concurrently (interleaved in a frame) using long packets received on the video and L3_MAIN interconnect ports because the DSI_VC_LONG_PACKET_HEADER_i register is used by the video mode. The register can be unprogrammed by the user to send long packets received on the L3_MAIN interconnect port only when there is no expected data on the video port. Software must program the register correctly to send sequentially long packets in video and command modes.

The word count (WC) defined in the DSI_VC_LONG_PACKET_HEADER_i register for the VC associated with the video port indicates the number of bytes to receive (one line or two lines can be used, depending on the WC and the size of the line buffer). The total size defined in the WC of the header register cannot exceed the size of the line buffer multiplied by the number of buffer lines.

The DSI_VC_LONG_PACKET_PAYLOAD_i register is used to provide payload data for long packets (checksum is calculated by hardware when the DSI_VC_CTRL_i[7] CS_TX_EN bit is set to 1; otherwise, the value is 0x00). The register is not used in video mode because payload data are provided by the video port.

Software must ensure that the following sequence for write accesses to the header and payload registers (DSI_VC_LONG_PACKET_HEADER_i and DSI_VC_LONG_PACKET_PAYLOAD_i, respectively) is followed:

- A long PH value with WC = 0 written in the DSI_VC_LONG_PACKET_HEADER_i register can be followed by any access.
- A long PH value with WC > 0 written in the DSI_VC_LONG_PACKET_HEADER_i register must be followed by one or more writes to the DSI_VC_LONG_PACKET_PAYLOAD_i register defined by the WC value before writing again to the same DSI_VC_LONG_PACKET_HEADER_i register.

CAUTION

If this sequence is not followed, no error is generated. Access to other DSI registers during this sequence is allowed.

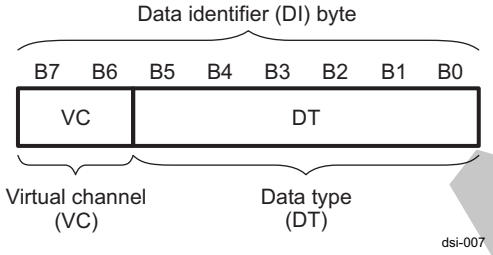
10.3.2.2.3 DSI Data Identifier

The data identifier byte contains the values for the virtual channel ID and data type, as shown in Figure 10-98. The virtual channel ID is contained in the 2 most-significant bits (MSBs) of the data identifier byte and identify the data as directed to one of four virtual channels. The value of the data type is contained in the 6 LSBs of the data identifier byte.

Figure 10-98. DSI Data Identifier Structure

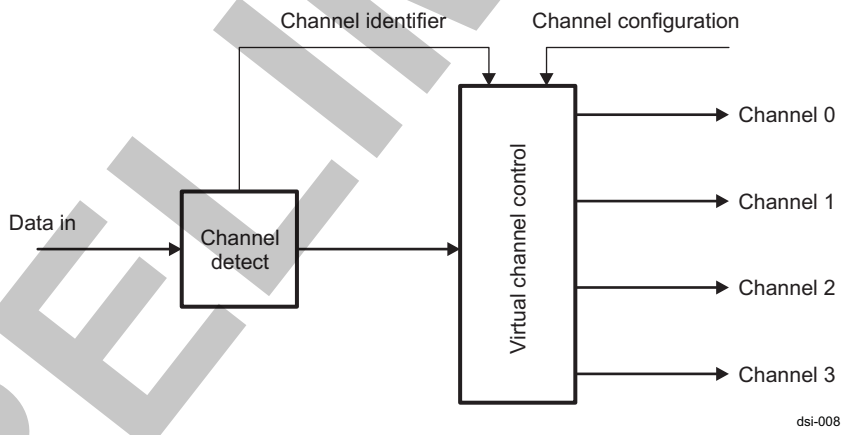


10.3.2.2.3.1 DSI VC ID – VC Field, DI[7:6]

The host can service up to four peripherals with tagged commands or blocks of data using the VC ID field of the header for packets targeted at different peripherals. The VC ID enables one serial stream to service two or more virtual peripherals by multiplexing packets onto a common transmission channel. Each packet sent in a single transmission has its own VC assignment and can be directed to different peripherals. The VC ID is defined in the DSI_VC_SHORT_PACKET_HEADER_i and DSI_VC_LONG_PACKET_HEADER_i registers for short and long packets, respectively. It will not be modified by hardware. There is one set of registers for each VC. Each set of registers defines the characteristics of the traffic between the host and the display associated with the VC.

Figure 10-99 shows the VC controller.

Figure 10-99. DSI VC Controller



10.3.2.2.3.2 DSI Data Type Field DT[5:0]

The data type field specifies whether the packet is long or short and identifies the packet format. The data type field, and the word count field for long packets, informs the receiver about how many bytes to expect in the rest of the packet. This is necessary because the beginning and end of a packet are not indicated by special packet start/end sync codes. This permits packets to convey arbitrary data, but it also requires the PH to specify the size of the packet.

10.3.2.2.4 DSI Synchronization Codes

Each frame can be identified by two synchronization codes:

- For the start of the vertical synchronization (VSS) pulse

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- For the end of the vertical synchronization (VSE) pulse

Each line can be identified by two synchronization codes:

- For the start of the horizontal synchronization (HSS) pulse
- For the end of the horizontal synchronization (HSE) pulse

The synchronization events are not required by the display (peripheral): they are optional. Users can program which synchronization events are generated to the display from the timings received from the DISPC in video mode. When data are received on the L3_MAIN interconnect port, the synchronization codes are not automatically generated by the protocol engine. They can be provided on the L3_MAIN interconnect port by writing to the registers with limited timing control. It is highly recommended to use the video port from the DISPC to receive the synchronization events to automatically generate short synchronization packets to the peripheral.

When the DSI protocol engine detects that the VSYNC signal from the DISPC transitions from INACTIVE to ACTIVE state, the VSS short packet replaces the following HSS corresponding to the following HSYNC synchronization short packet (if the generation is enabled).

When the transition from ACTIVE to INACTIVE state is detected, the VSE short packet is generated (if the generation is enabled), replacing the HSE synchronization packet corresponding to the following HSYNC.

When the DSI protocol engine detects that the HSYNC signal from the DISPC transitions from INACTIVE to ACTIVE state, the HSS short packet is generated (if the generation is enabled).

When the transition from ACTIVE to INACTIVE state is detected, the HSE short packet is generated (if generation is enabled).

For the first frame, any HSYNC and data received on the video port before the first VSYNC must be ignored. Because the first VSYNC sent to the display is also recognized as an HSYNC for the first line, there is no HSYNC sent for the first line. To send the synchronization codes, the DSI protocol engine uses short packets. Table 10-511 lists the 6-bit DT synchronization code values.

Table 10-511. DSI Synchronization Codes

Synchronization Code	Value	Comments
Vertical sync start code (VSS)	0x1	Optional
Vertical sync end code (VSE)	0x11	Optional
Horizontal sync start code (HSS)	0x21	Optional
Horizontal sync end code (HSE)	0x31	Optional

10.3.2.2.5 DSI Blanking

To keep the DSI link in HS mode while using video mode during blanking periods, long blanking packets are sent to the display. The DSI_VM_TIMINGx (where x = 1 to 8) registers define the size of the long blanking packets after:

- Horizontal sync start code (short packet)
- Horizontal sync end code (short packet)
- Vertical sync start code (short packet)
- Vertical sync end code (short packet)
- Pixels (long packet)

Table 10-512 defines the short packet values for the synchronization packets:

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 10-512. DSI Sync Short Packet Values

VC ID	Sync Code	Header (First Byte)	Header (Second Byte): Data Field LSB	Header (Third Byte): Data Field MSB	Header (ECC)
0x0	0x1	0x1	0x0	0x0	See Note following this table.
	0x11	0x11			
	0x21	0x21			
	0x31	0x31			
0x1	0x1	0x41			
	0x11	0x51			
	0x21	0x61			
	0x31	0x91			
0x2	0x1	0x81			
	0x11	0x81			
	0x21	0xA1			
	0x31	0xB1			
0x3	0x1	0xC1			
	0x11	0xD1			
	0x21	0xC1			
	0x31	0xF1			

NOTE:

- If the ECC is enabled by setting the DSI_VC_CTRL_i[8] ECC_TX_EN bit to 1 for the VC in video mode, the ECC value is calculated; otherwise, 0x00 is used for the blanking long packets and sync short packets. If the CRC is enabled by setting the DSI_VC_CTRL_i[7] CS_TX_EN bit to 1 for the VC in video mode, the checksum value is calculated; otherwise, 0x00 is used for the blanking long packets.
- In other cases, when the DSI_VC_CTRL_i[7] CS_TX_EN bit is set to 0, the value 0x00 is always used for the CRC (long packets). When the DSI_VC_CTRL_i[8] ECC_TX_EN bit is set to 0, the value 0x00 is used for the ECC for short and long packets, except when the header is provided by the register, because the ECC field is available in the register. It can be used to generate invalid ECC values when the header is provided by the register.

The DSI link (lanes and clock separately) can be put in ULPS. While using the blanking values formerly defined, the packets (short and long) are considered in HS mode.

Timing parameters VSA, VBP, VFP, HSA, HBP, HFP, VACT, and t_L are defined in the DSI_VM_TIMING1 through DSI_VM_TIMING8 registers. HSA, HBP, HFP, and t_L are defined using the byte clock unit (TXBYTECLKHS – HS transmit byte clock generated by DSI_PHY_DSS_x) and also in low-power clock cycles (TxClkEsc). VSA, VBP, VFP, and VACT are defined by the number of lines. When the HS blanking packets are sent during the blanking periods, the parameters are used to determine the blanking packet payload size (considering the 4-byte header and the 2-byte checksum).

The configuration of the DISPC timing generator must be used when the DISPC timings are used to generate DSI HS video mode transfer.

Special care must be taken in the case of the last line of the frame. The LPS transition is required when the link is in HS mode for the whole frame.

When BTA is sent for the data packets, the following blanking period cannot be used to send any data from the TX FIFO. When the blanking period starts with one HS packet from one VC, it can be followed only by another HS packet from the same VC, or by a trigger (for example, BTA). When there is no more HS data to send for this VC, the lane is in LPS.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

When the blanking period starts with one LP packet from one VC, it can be followed only by another LP packet from the same VC, by another VC, by trigger (BTA, for example), or by extra LP NULL packets. If the trigger is sent, it is not possible to send any more data. When there is no more data from the TX FIFO to send in LP mode or the trigger has been sent, the lane is put into LPS. If the lanes must be kept in HS mode during blanking periods (except for the last blanking period of the frame), the HS blanking packets must be used. If one trigger is sent at the beginning of the blanking period, the rest of the blanking period is in LPS.

Figure 10-100 and Figure 10-101 show a nonburst transfer in DSI video mode with and without VE and HE, respectively. Figure 10-102 shows a burst transfer in DSI video mode without VE and HE.

10.3.2.2.7 DSI VCs

The DSI protocol layer transports VCs. VCs separate different data flows, which are interleaved in the same data stream. Each VC is identified by a unique channel identification number in the PH. The channel identification number is encoded in 2 bits. The DSI protocol engine determines the channel identifier number to be used to generate the PH and multiplexes the interleaved data streams. The DSI protocol engine supports up to four concurrent VCs. Table 10-513 summarizes the VC values used for each channel.

Table 10-513. DSI VC Values

VC Number	Value
VC 0	0x0
VC 1	0x1
VC 2	0x2
VC 3	0x3

If multiple displays are connected to a single DSI port on the host, a hub can be used to route the data stream to the appropriate display based on the VC ID. Typically, VC ID 0x0 is used for the primary display and 0x1 is used for the secondary. The hub may have its own VC ID to provide communication capability between the host and the hub.

There is one set of registers for each VC. The attributes of the VC define the following characteristics:

- Transfer mode (DSI_VC_CTRL_i[4] MODE bit):
  - Video mode
  - Command mode
- Data type
- Source (DSI_VC_CTRL_i[1] SOURCE bit)
  - Video port
  - Slave interconnect port
- HS or LP forward transmission
- Automatic BTA generation
  - Short packets (DSI_VC_CTRL_i[2] BTA_SHORT_EN bit)
  - Long packets (DSI_VC_CTRL_i[3] BTA_LONG_EN bit)
- DMA request configurations for RX and TX
  - DMA request number (DSI_VC_CTRL_i[29:27] DMA_RX_REQ_NB bit field for RX FIFO and DSI_VC_CTRL_i[23:21] DMA_TX_REQ_NB bit field for TX FIFO)
  - DMA threshold (DSI_VC_CTRL_i[26:24] DMA_RX_THRESHOLD bit field for RX FIFO and DSI_VC_CTRL_i[19:17] DMA_TX_THRESHOLD bit field for TX FIFO)
- Mode speed (DSI_VC_CTRL_i[9] MODE_SPEED bit)
- ECC transmission (DSI_VC_CTRL_i[8] ECC_TX_EN bit)
- CS transmission (DSI_VC_CTRL_i[7] CS_TX_EN bit)

NOTE: The VC ID is not calculated by the DSI module but is provided while writing into the DSI_VC_SHORT_PACKET_HEADER_i and DSI_VC_LONG_PACKET_HEADER_i registers.

10.3.2.3 DSI Multilane Layer

A layer consists of lane splitter logic to split the incoming byte stream into a serial stream. The bits are sent with the LSB first. The number of active lanes is configurable through a register. The order of the lanes is configurable. The number of lanes can be changed only in ULPS or when all data lanes are in STOP state.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

10.3.2.3.1 DSI SoT and EoT in Multilane Configurations

Because a HS transmission is composed of an arbitrary number of bytes that may not be an integer multiple of the number of lanes, some lanes may run out of data before others. Therefore, the lane management layer, as it buffers up the final set of less-than-N bytes, deasserts its valid data signal into lanes for which there is no further data. Although all lanes start simultaneously with parallel start-of-transmissions (SoTs), each lane operates independently and may complete the HS transmission before the other lanes, sending an end-of-transmission (EoT) one cycle (byte) earlier.

10.3.2.3.2 DSI Lane Splitter

The lane splitter can split the byte stream into two, three, or four lanes (for one lane, the splitter is bypassed). Figure 10-106 through Figure 10-109 show the byte position in each serial link for one-, two-, three-, and four-data lane configurations. The byte stream always starts from the first lane. It finishes on one of the lanes, depending on the number of bytes to send and the number of lanes. The splitter module is used only when packets are sent using HS mode. In LS mode, only the first data lane is used.

Figure 10-106. DSI Four-Data Lane Configuration

10.3.2.4 DSI Pixel Data Formats

This section describes how the DSI-supported pixel data formats in video mode are transmitted over the serial interface. The DSI protocol engine can cope with all data formats if the data line length sent through the DSI physical protocol is a multiple of a pixel. This condition is required for the DSI protocol engine to work properly.

10.3.2.4.1 DSI Pixel Data Formats in Video Mode

The host can send different pixel formats in video mode. Table 10-514 lists the pixel formats supported by the DSI in video mode.

Table 10-514. DSI Pixel Data Format in Video Mode

Mode	Description
RGB888 (using 24-bit container)	RGB888
RGB666 (using 24-bit container)	RGB666
RGB666 (18-bit packet using 18-bit container)	RGB666_PACKET
RGB565 (using 16-bit container)	RGB565

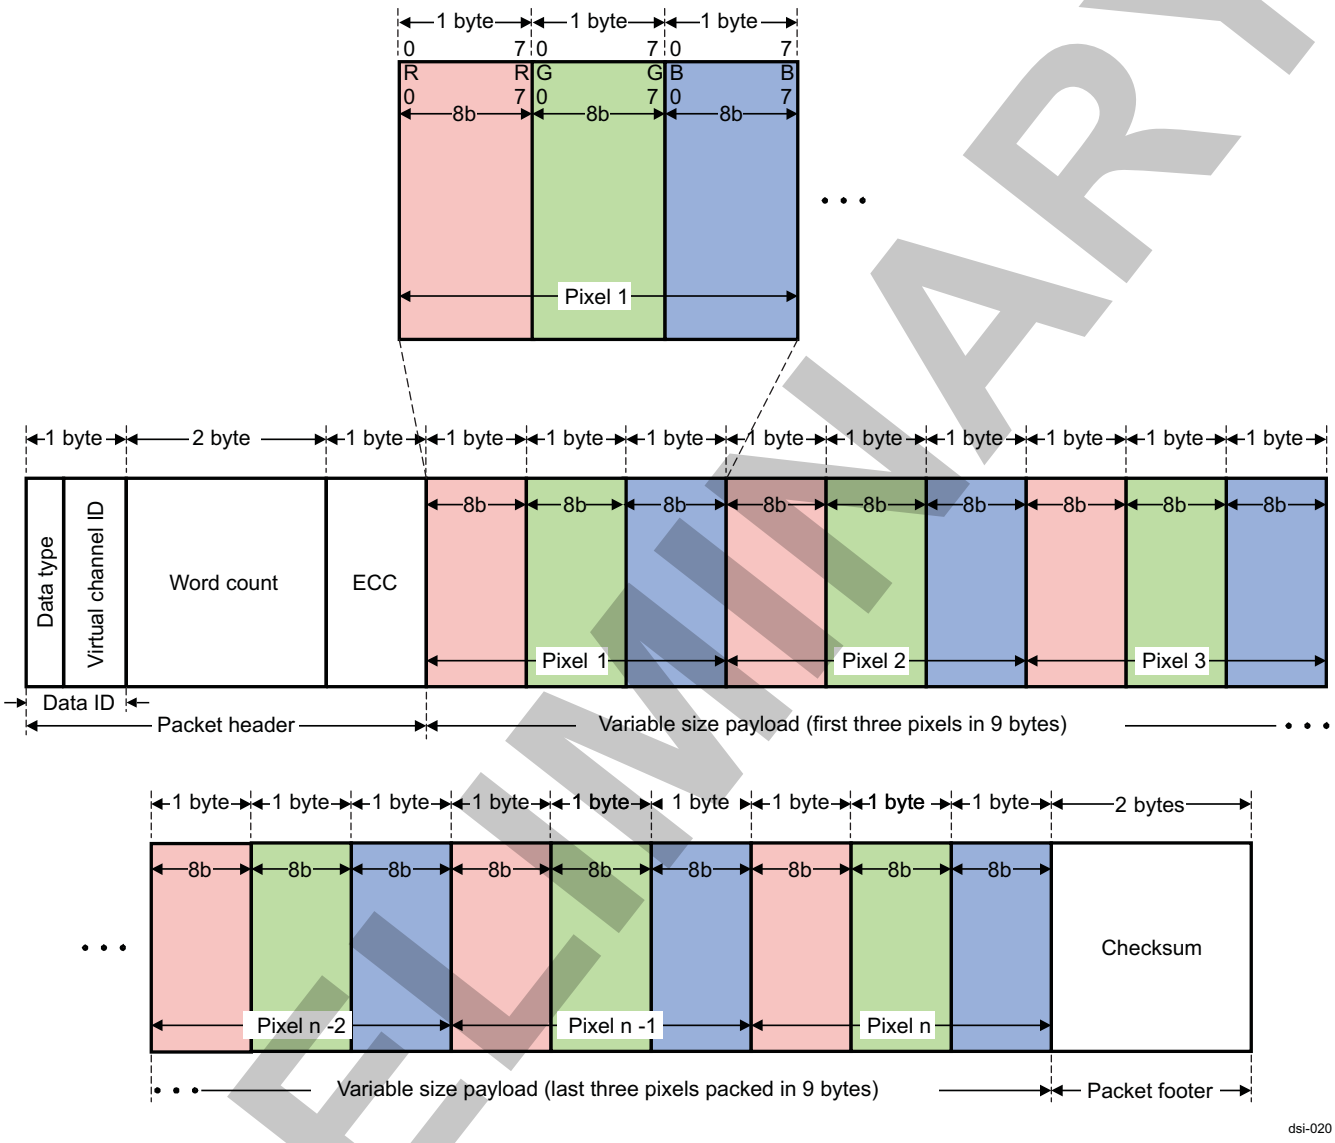
10.3.2.4.2 DSI 24 bpp – RGB Color Format, Long Packet (Video Mode)

Figure 10-111 shows the RGB888 format.

Figure 10-111. DSI 24-bpp RGB Color Format, Long Packet (Video Mode)



Packed-pixel stream, 24-bit format is a long packet used to transmit image data formatted as 24-bit pixels to a video mode display module. The packet consists of the data ID byte, a 2-byte WC, an ECC byte, a payload of length WC bytes, and a 2-byte checksum. The pixel format is R (8 bits), G (8 bits), and B (8 bits), in that order. Each color component occupies 1 byte in the pixel stream; no components are split across byte boundaries. Within a color component, the LSB is sent first and the MSB last.

10.3.2.4.3 DSI 24 bpp - RGB Color Format, Long Packet (Command Mode)

Figure 10-112 shows the RGB888 format.

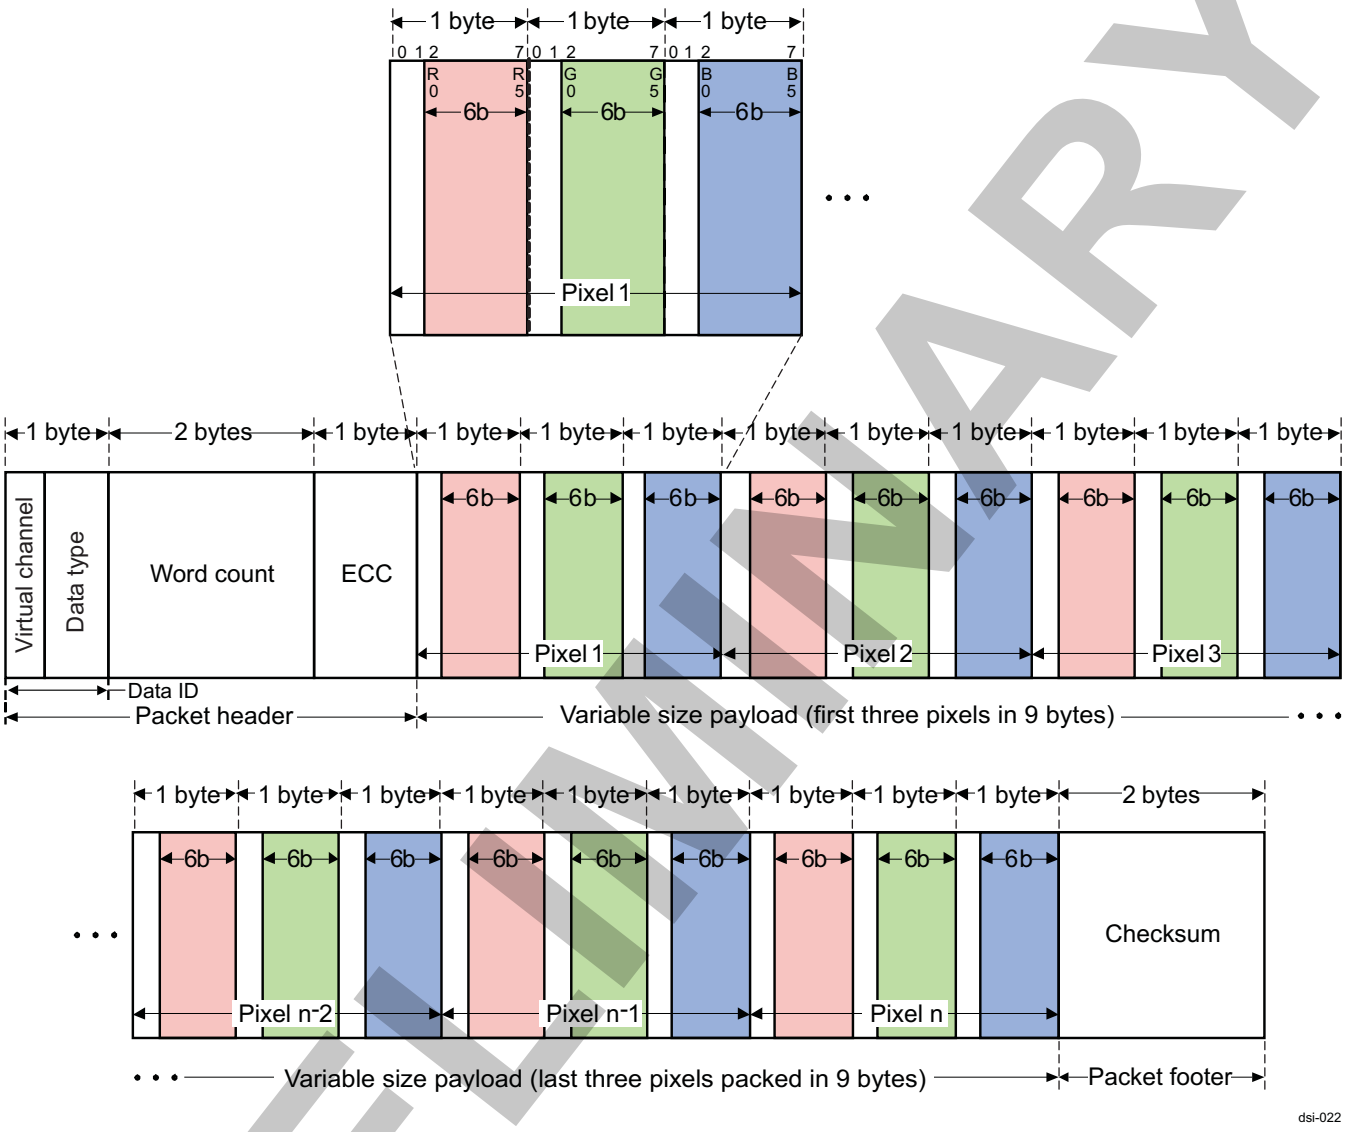
10.3.2.4.4 DSI 18 bpp (Loosely Packed) – RGB Color Format, Long Packet (Transparent for DSI Protocol Engine) (Video Mode)

Figure 10-113 shows the RGB666 format.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-113. DSI 18-bpp (Loosely Packed) RGB Color Format, Long Packet (Transparent for DSI Protocol Engine) (Video Mode)



In 18-bit loosely packed pixel format, each R, G, and B color component is 6 bits but is shifted to the upper bits of the byte, such that the valid pixel bits occupy bits [7:2] of each byte. Bits [1:0] of each payload byte representing active pixels are ignored. As a result, each pixel requires 3 bytes as it is transmitted across the link. This requires more bandwidth than packed format but requires less shifting and multiplexing logic in the packing and unpacking functions on each end of the link. This format is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels. The packet consists of the data ID byte, a 2-byte WC, an ECC byte, a payload of length WC bytes, and a 2-byte checksum. The pixel format is R (6 bits), G (6 bits), and B (6 bits), in that order. Within a color component, the LSB is sent first and the MSB last.

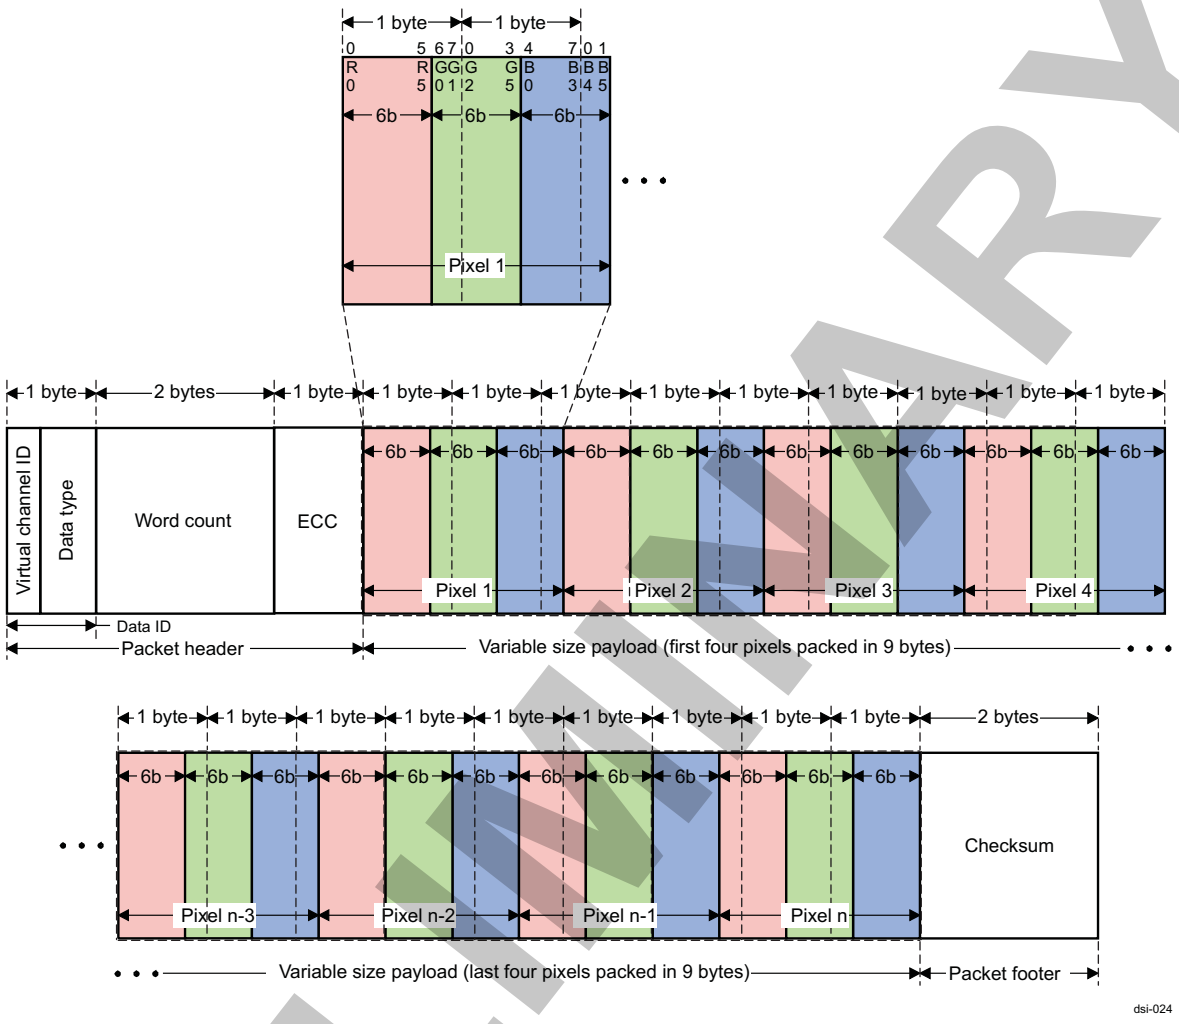
Figure 10-115. DSI 18-bpp (Packed) RGB Color Format, Long Packet (Video Mode)



Packed pixel stream 18-bit format is a long packet. It is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels The packet consists of the data ID byte, a 2-byte WC, an ECC byte, a payload of length WC bytes, and a 2-byte checksum. The pixel format is R (6 bits), G (6 bits), and B (6 bits), in that order. Within a color component, the LSB is sent first and the MSB last. With this format, it is strongly recommended that the total line width be a multiple of 4 pixels (9 bytes). This format is not supported in command mode.

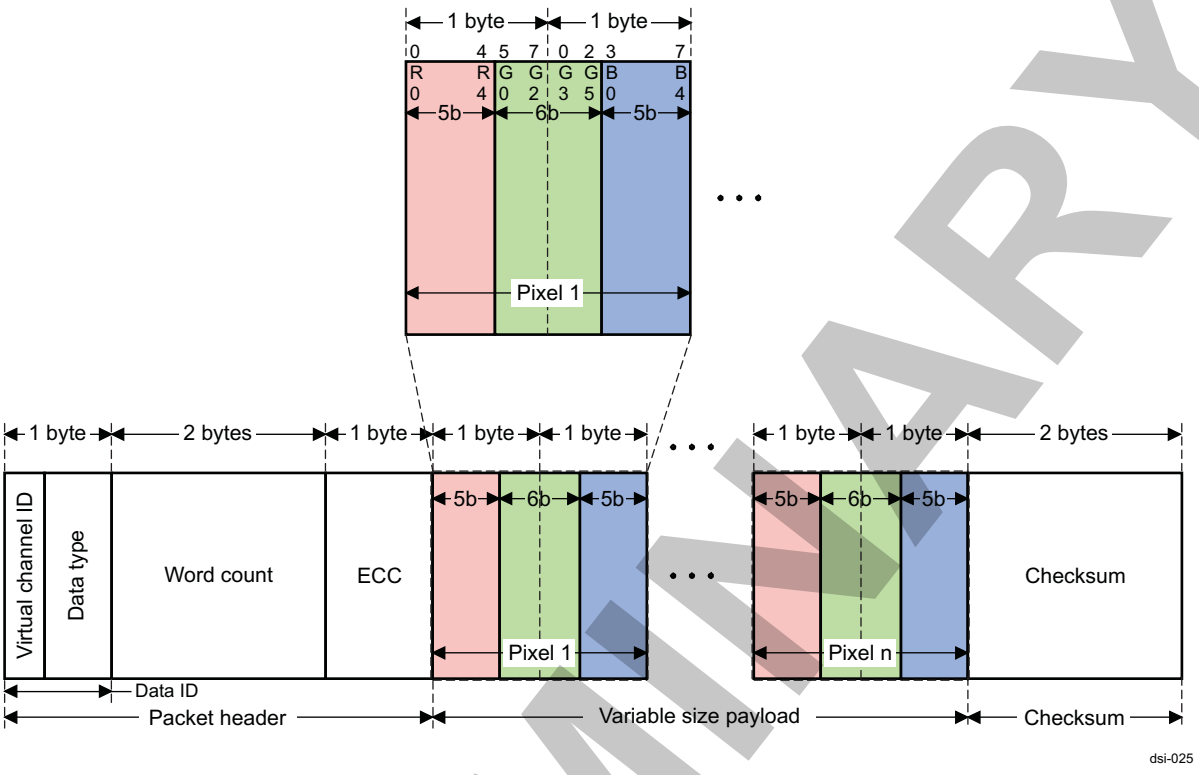
Figure 10-116. DSI 16-bpp RGB Color Format, Long Packet (Video Mode)



Packed-pixel stream, 16-bit format is a long packet used to transmit image data formatted as 16-bit pixels to a video mode display module. The packet consists of the data ID byte, a 2-byte WC, an ECC byte, a payload of length WC bytes, and a 2-byte checksum. The pixel format is R (5 bits), G (6 bits; split across 2 bytes), and B (5 bits), in that order. Within a color component, the LSB is sent first and the MSB last.

NOTE: For more information about the DSI1_A and DSI1_C video port clocks (VPn_CLK and VPn_PCLK, where n = 1 or 2), see Section 10.3.4.4.5, *DSI Video Port Interface*

NOTE: For the frequency ratings of the various DSI clocks, see Display Subsystem Clocks, in *Display Subsystem*.

NOTE: To enable the bypass input for the DSI_PHY_DSS_A or DSI_PHY_DSS_C module, set the DSI_PLL_CONFIGURATION2[15] BYPASSEN bit to 1.

10.3.4.3 DSI Interrupt Requests

The DSI protocol engine requires a single interrupt line. The DSI_IRQSTATUS register indicates the general interrupt events. Each VC and PHY has a dedicated interrupt register: DSI_VC_IRQSTATUS_i and DSI_COMPLEXIO_IRQSTATUS, respectively.

Table 10-520 lists the DSI global interrupt events.

Table 10-520. DSI Global Interrupts

IRQ Name	Description
RESYNCHRONIZATION_IRQ	Resynchronization in video mode
TA_TO_IRQ	Turnaround timer expired
SYNC_LOST_IRQ	Synchronization with video port is lost (video mode only).
ACK_TRIGGER_IRQ	Acknowledge trigger is received.
TE_TRIGGER_IRQ	TE PHY trigger is received.
WAKEUP_IRQ	Occurs when the SWakeUp signal is asserted.
HS_TX_TO_IRQ	HS TX time-out interrupt
LP_RX_TO_IRQ	LS RX time-out interrupt
COMPLEXIO_ERR_IRQ	Error signaling from DSI PHY: The interrupt is triggered when an error is received from the DSI PHY (events are defined in DSI_COMPLEXIO_IRQSTATUS).
PLL_RECAL_IRQ	PLL recalibration event (assertion of DSIRecal signal from the DSI PLL control module)
PLL_UNLOCK_IRQ	PLL unlock event (deassertion of DSILock signal from the DSI PLL control module)
PLL_LOCK_IRQ	PLL lock event (assertion of DSILock signal from the DSI PLL control module)
VIRTUAL_CHANNEL3_IRQ	VC 3 error signaling from DSI VC 3: The interrupt is triggered when an error is received from DSI VC 3 (events are defined in DSI_VC_IRQENABLE_i where i = 3).
VIRTUAL_CHANNEL2_IRQ	VC 2 error signaling from DSI VC 2: The interrupt is triggered when an error is received from DSI VC 2 (events are defined in DSI_VC_IRQENABLE_i where i = 2).
VIRTUAL_CHANNEL1_IRQ	VC 1 error signaling from DSI VC 1: The interrupt is triggered when an error is received from DSI VC 1 (events are defined in DSI_VC_IRQENABLE_i where i = 1).
VIRTUAL_CHANNEL0_IRQ	VC 0 error signaling from DSI VC 0: The interrupt is triggered when an error is received from DSI VC 0 (events are defined in DSI_VC_IRQENABLE_i where i = 0).
TE0_LINE_IRQ	TE detected on TE0 CMOS input signal
TE1_LINE_IRQ	TE detected on TE1 CMOS input signal

NOTE: For information about other internal DSI interrupt events, see Table 10-538 and Table 10-547 .

10.3.4.4 DSI Protocol Engine

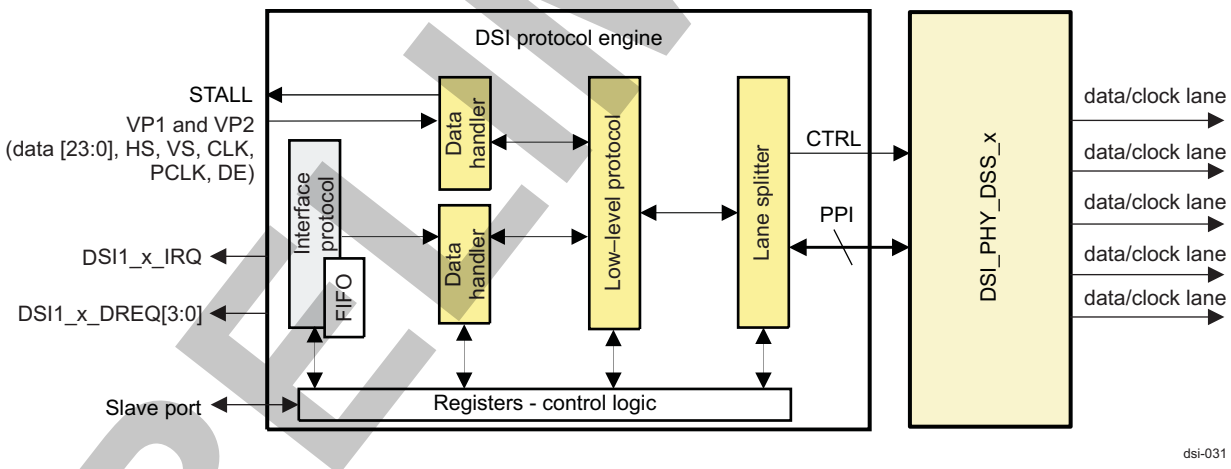
NOTE: Copyright 2005-2008 MIPI Alliance, Inc. All rights reserved. MIPI Alliance Member Confidential.

The DSI protocol engine integrates the DSI with the display through the DSI_PHY_DSS_x module, local interconnect interface, and video interface from the DISPC. The DSI_PHY_DSS_x module is described in Section 10.3.4.6, *DSI PHY*. The DSI transmitter (protocol engine + PHY) port can be connected to multiple displays using a single DSI host port. The DSI protocol engine controls the DSI PLL control module described in Section 10.3.4.5, *DSI PLL Controllers*. The DSI transmitter port can be used in video mode or/and command mode.

10.3.4.4.1 DSI Protocol Overview

The DSI protocol engine receives data from the DISPC video port and/or the L3_MAIN interconnect slave port, encapsulates them with the VC ID, generates the ECC and checksum, and splits the data into byte streams to the DSI_PHY_DSS_x to be sent using LS or HS protocol. The DSI protocol engine receives data and acknowledges from the panel using the same DSI link in case of bidirectional panel. Multiple data streams can be interleaved to support multiple panels connected to the same host DSI port. Figure 10-121 shows the DSI protocol engine, with an example of data lane and clock lane ordering. It is possible to configure other orders through registers as described in Section 10.3.2.1.1, *Data/Clock Configuration*.

Figure 10-121. DSI Protocol Engine



NOTE: The order of the PHY pairs (clock and data lanes) is informative. Each PHY pair can be clock or data. DSI PHY receives the configuration for the pin order and the differential ± in a pair from the settings in the DSI_COMPLEXIO_CFG1 register.

10.3.4.4.2 DSI Global Register Controls

Before receiving data from the DSI PHY, the DSI_PHY_DSS_x SCP registers in the DSI PHY must be configured. Table 10-521 lists the register access width limitations for all the DSI modules.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 10-521. DSI Register Access Width Limitations

Register Name	Register Access Width
All DSI PHY registers (DSI_PHY_DSS_x SCP)	32-bit only
All DSI PLL control module registers	32-bit only
DSI_VC_LONG_PACKET_HEADER_i	32-bit only
DSI_VC_SHORT_PACKET_HEADER_i	32-bit only
DSI_VC_LONG_PACKET_PAYLOAD_i	16- and 32-bit
All other DSI protocol engine registers	8-, 16-, and 32-bit

CAUTION

If a different access width than listed in Table 10-521 is used, an interface error is generated in response to the write using SResp = ERR.

The DSI protocol engine is globally controlled by the DSI_CTRL register. The interface to the DSI PHY is enabled by setting the DSI_CTRL[0] IF_EN bit. When the interface is disabled, it is possible to provide data to the TX FIFO and read pending data in the RX FIFO. When the DSI_CTRL[0] IF_EN bit is set to 1, the pending packets are sent to the DSI PHY, and the data transfer from the video port is ignored until the first vertical sync event is received.

When the DSI_CTRL[0] IF_EN bit is reset by software, the DSI protocol engine must finish the transfer of the pending data in the TX FIFO and wait for a response if BTA has been sent (the protocol engine is in receive mode); hardware then resets the DSI_CTRL[0] IF_EN bit. When using video mode, the VC associated with the video port must be enabled before enabling the interface according to the following sequence:

1. The DSI_CTRL[0] IF_EN bit is equal to 0.
2. Enable the VC associated with video mode by setting the DSI_VC_CTRL_i[0] VC_EN bit.
3. Set the DSI_CTRL[0] IF_EN bit to 1.

10.3.4.4.3 DSI Transfer Modes

Two main transfer modes are supported by the DSI modules:

- Video mode: Pixels are received from the video port (VP1 or VP2.) There are some real-time constraints (pixels must be sent at the pixel frequency required by the panel module).
- Command mode: Pixels can be received from the video port or from the L3_MAIN interconnect slave port. There are no real-time constraints except that the TE must be avoided by starting the transfer at the correct time during the scan of the display and that it must be fast enough.

10.3.4.4.3.1 DSI Video Mode

Video mode refers to the MIPI display pixel interface (DPI) standard. The sync events and pixels must be sent according to the display mode timings. Data is received from the video ports. The DISPC fetches the data from the system memory and provides it to the DSI protocol engine through VP1 or VP2. The short packets used for the sync event use precalculated 32-bit values. The long packets are constructed using the header defined in the DSI_VC_LONG_PACKET_HEADER_i registers. In case of synchronization short packets for video mode, because hardware generates short packets without using the DSI_VC_SHORT_PACKET_HEADER_i register, if the DSI_VC_CTRL_i[8] ECC_TX_EN bit is set, the ECC is calculated; otherwise, 0 is used. This feature is used to generate incorrect ECC for debugging purposes and to ease the check of the link and peripheral error detection and correction.

The DSI_VM_TIMING1 through DSI_VM_TIMING8 registers define the timings of the video mode.

The DSI_VM_TIMING2[27:24] WINDOW_SYNC bit field defines the synchronization period. The recommended value is 0x4 based on the implementation of the resynchronization scheme.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The DSI_CTRL[20] BLANKING_MODE bit defines whether long blanking packets or LPS are used during the blanking periods (except HFP, HBP, and HSA defined by other bits) when there is no pending data in TX FIFO ready to be sent. Software must ensure that there is no data in the TX FIFO, no BTA, no RESET trigger sent, and the DSI_VC_CTRL_i[9] MODE_SPEED bit is set to 1 (HS mode) to keep the video mode transfer in HS mode during blanking periods (except for the last blanking period, because it is required to go to LPS at least once per frame).

The following bits define whether during these blanking packets data from TX FIFO or long blanking packets are sent:

- DSI_CTRL[21] HFP_BLANKING_MODE
- DSI_CTRL[22] HBP_BLANKING_MODE
- DSI_CTRL[23] HSA_BLANKING_MODE

To ensure that the writes to the DSI_VC_LONG_PACKET_HEADER_i register are handled correctly as header information for video mode long packets, the following registers must be programmed:

- DSI_VC_CTRL_i[0] VC_EN bit set to 0
- DSI_VC_CTRL_i[4] MODE bit set to 1
- DSI_VC_LONG_PACKET_HEADER_i register access
- DSI_VC_CTRL_i[0] VC_EN bit set to 1

NOTE: The hardware ignores the DSI_VC_CTRL_i[1] SOURCE and DSI_VC_CTRL_i[9] MODE_SPEED bits when video mode is selected (the DSI_VC_CTRL_i[4] MODE bit is set to 1).

The SYNC_LOST_IRQ and RESYNCHRONIZATION_IRQ interrupt events indicate whether or not the DSI protocol engine has been able to resynchronize the video port timing to its own timing base. The RESYNCHRONIZATION_IRQ indicates to the software user that the video port works but the configuration of the timings for the DISPC and for DSI protocol engine may need to be modified to avoid the resynchronization. The SYNC_LOST_IRQ and RESYNCHRONIZATION_IRQ events, respectively, can be monitored in the DSI_IRQSTATUS[18] SYNC_LOST_IRQ and DSI_IRQSTATUS[5] RESYNCHRONIZATION_IRQ status bits.

10.3.4.4.3.2 DSI Command Mode

The command mode refers to the MIPI display command set (DCS) standard. The commands, parameters, and pixels are sent to the display module with limited real-time constraints (as defined in Section 10.3.4.4.3.1, *Video Mode*). The pixels can be provided on one of the two video ports by the DISPC or on the L3_MAIN interconnect slave port.

The DSI_VC_LONG_PACKET_HEADER_i registers are used for the header of long packets; the DSI_VC_SHORT_PACKET_HEADER_i registers are used for short packets.

For the payload, the DSI_VC_LONG_PACKET_PAYLOAD_i register is used. Each 32-bit payload data is written to the DSI_VC_LONG_PACKET_PAYLOAD_i register from the MPU subsystem or DMA_SYSTEM. It is buffered to send packets with a higher rate than the L3_MAIN interconnect frequency can provide. If the DSI_VC_CTRL_i[30] DCS_CMD_ENABLE bit is set to 1, the word count defined in the DSI_VC_LONG_PACKET_HEADER_i register is used to determine the number of bytes to be sent using the DSI_VC_LONG_PACKET_PAYLOAD_i register minus the size of the DCS command header added by the protocol engine at the beginning of the payload (also sent using the DSI_VC_LONG_PACKET_PAYLOAD_i register). If the DSI_VC_CTRL_i[30] DCS_CMD_ENABLE bit is set to 0, the word count defined in the DSI_VC_LONG_PACKET_HEADER_i register is used to determine the number of bytes to be sent using the DSI_VC_LONG_PACKET_PAYLOAD_i register.

The DSI_VC_CTRL_i[11:10] OCP_DATA_BUS_WIDTH bit field is used to define the size of the data on the L3_MAIN interconnect slave port for the write access (read access to the RX FIFO is not affected by the bit field value):

- 0x0: 16-bit data width (LSB of the 32-bit interface port data bus)
- 0x1: 24-bit data width (LSB of the 32-bit interface port data bus)

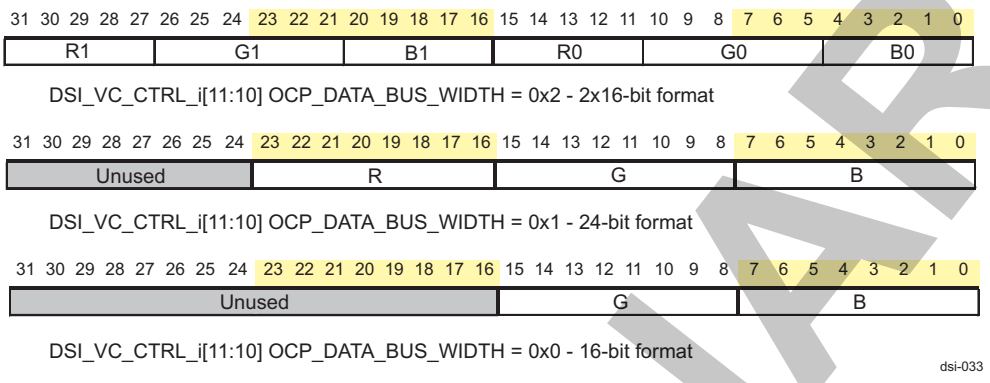
PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- 0x2: 2 × 16-bit data width (first pixel on the LSB of the 32-bit interface port data bus and second pixel on the MSB of the 32-bit interface port data bus for the same interface access)
- 0x3: 32-bit data width (no bit, no byte, no pixel manipulation)

Figure 10-122 shows the different data width configurations of the L3_MAIN interconnect slave port.

Figure 10-122. DSI Interface Data Configuration



NOTE: To provide 18-bit pixel loosely packed format to the L3_MAIN interconnect slave port, the DSI_VC_CTRL_i[11:10] OCP_DATA_BUS_WIDTH bit field must be set to 0x1. The 18-bit pixel packed format is not supported in case of command mode on the L3_MAIN interconnect slave port.

The write into the DSI_VC_LONG_PACKET_HEADER_i register is required before accessing the DSI_VC_LONG_PACKET_PAYLOAD_i register. The DSI protocol engine must extract the length of the payload and discard the extra data sent using the DSI_VC_LONG_PACKET_PAYLOAD_i register. Writes into the DSI_VC_LONG_PACKET_HEADER_i register are valid only if the VC is enabled; otherwise, the write is ignored. When receiving pixels on the video port, only the DSI_VC_LONG_PACKET_HEADER_i register is used. The video port pixels are used for the payload.

10.3.4.4.3.2.1 DSI Command Mode TX FIFO

The single TX FIFO is used to store data from the L3_MAIN interconnect before sending it to the panel. The configuration of the FIFO for a specific VC must be done only when the VC is disabled.

The VC must not be enabled when data is still pending in the TX FIFO for the corresponding space allocated for the VC from the previous active period. When the VC space in the TX FIFO is empty, the VC can be enabled.

For each VC, two dedicated registers (DSI_VC_LONG_PACKET_HEADER_i and DSI_VC_LONG_PACKET_PAYLOAD_i) are used to provide data for long packets. The DSI_VC_SHORT_PACKET_HEADER_i register is used to provide data for short packets (32 bits long).

For each long packet, the DSI_VC_LONG_PACKET_HEADER_i register must be written first, followed by the DSI_VC_LONG_PACKET_PAYLOAD_i register. The only exception is when the word count defined in the header equals 0. In that case, it is not required to write into the payload register. For consecutive long packets, the header must be written into the DSI_VC_LONG_PACKET_HEADER_i register even if the value remains the same.

The TX FIFO stores all the pending bytes to be sent to the peripheral(s). Multiple receivers can be addressed using the VC capability.

The 32-bit write requests for each VC to the TX FIFO are kept in order while sending the data to the DSI_PHY_DSS_x inside the VC requests. The only exception is the last 32-bit write for the last bytes of the payload data, because it can be 1, 2, 3, or 4 bytes.

When the last transfer is a 32-bit write, but the number of valid bytes is only 1, 2, or 3 (calculated using the header word count and the number of bytes are received for the payload), hardware stores the 32-bit value into the TX FIFO but the invalid bytes are not sent and are discarded.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

When the word count defined in the DSI_VC_LONG_PACKET_HEADER_i register is not a multiple of the request threshold value defined in the DSI_VC_CTRL_i[19:17] DMA_TX_THRESHOLD bit field, 32-bit requests and/or bytes are discarded by hardware to store in FIFO only the exact number of valid bytes.

The triggering event to send data to the DSI link is one of the following events:

- All bytes have been received in the FIFO (header + payload).
- The space of the FIFO allocated for the VC is full.
- The space of the FIFO allocated for the VC is not enough to request more data using DMA request (the threshold value is bigger than the space left in the TX FIFO for the VC).
- When the VC is disabled, the remaining bytes in the FIFO are sent to the DSI link.

NOTE: In case video mode is active, the blanking period must be large enough to allow the transfer of the packet(s).

Sequential arbitration must be set (DSI_CTRL[3] TX_FIFO_ARBITRATION = 0x1) if only one VC is used to send multiple packets during the same blanking period.

When consecutive packets must be sent to HS mode, to ensure that there is no LP transition between them, at least one of the following conditions must be valid:

- Packets from the same VC
- Short packets or long packets with a payload size multiple of 4 bytes

To stop a transfer immediately when packets are being transferred from the TX FIFO to DSI_PHY_DSS_x, a flush of the FIFO is necessary. It can be required in a dead-lock situation to flush the FIFO even if bytes are still in the FIFO. In that case, it is necessary to ensure having a known state of the whole DSI protocol engine module (software reset may be required) to the start of a new transfer through the TX FIFO.

To flush the FIFO (discard the data) for some pending bytes:

1. Change the size of the space of FIFO to 0 by writing DSI_TX_FIFO_VC_SIZE VCi_FIFO_SIZE bit fields (where i is the VC number from 0 to 3).
2. Disable the VC by resetting the DSI_VC_CTRL_i[0] VC_EN bit to 0.
3. Wait for DSI_VC_CTRL_i[15] VC_BUSY = 0 (VC_BUSY is set to 0 after TX FIFO flush is done).

It is necessary to check that there is no pending request before changing the size of the allocated FIFO for the VC by reading the relevant DSI_VC_CTRL_i[15] VC_BUSY bit or by using the interrupt PACKET_SENT_IRQ. This interrupt is monitored by reading the DSI_VC_IRQSTATUS_i[2] PACKET_SENT_IRQ status bit.

The DSI_CTRL[3] TX_FIFO_ARBITRATION bit defines the arbitration scheme:

- Round-robin between enabled VCs with pending ready requests (that is, all bytes for the packets are in the FIFO or the space of the FIFO for the VC is full) starting from the VC that has the lowest VC ID number.
- Sequential: All the pending ready requests for one VC are sent before moving to another VC. The condition of "space of the FIFO is full" is evaluated after the end of each packet.

To use in-order for all requests for all channels, a single VC must be used. (The VC ID defined in the header provided to the hardware using the DSI_VC_LONG_PACKET_HEADER_i or DSI_VC_SHORT_PACKET_HEADER_i register is not used and not modified by the DSI protocol engine.)

The DSI_TX_FIFO_VC_SIZE register defines the allocated number of 33-bit values for each VC in the TX FIFO and the start address for each VC. The size of the space allocated in the TX FIFO is defined by the DSI_TX_FIFO_VC_SIZE register VCi_FIFO_SIZE bit field. It must be a multiple of the threshold defined in the DSI_VC_CTRL_i[19:17] DMA_TX_THRESHOLD bit field. To change the size of the space of the memory allocated for a specific VC, the VC must be disabled by setting the DSI_VC_CTRL_i[0] VC_EN bit to 0. The whole FIFO cannot be used by all the VCs at the same time because a VC can be disabled to change one or multiple parameters. Software users must configure the start address and size for each VC correctly.

Table 10-522 lists the corresponding values for the size of the space allocated in the FIFO.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

Table 10-522. DSI VC TX FIFO Size Values

DSI_TX_FIFO_VC_SIZE.VCi_FIFO_SIZE (where i = 0, 3)	Space Size (up to the size of the FIFO)
0	0 × 33 bits
1	32 × 33 bits
2	64 × 33 bits
3	96 × 33 bits
4	128 × 33 bits

NOTE: TX FIFO is 128 × 33 bits. Therefore, the sum of all VC FIFO allocations cannot exceed 128 × 33 bits.

CAUTION

Bit 32 of each location in the FIFO is used by the DSI protocol engine to tag the data in the TX FIFO. It is for internal use only.

Table 10-523 lists the start address of the space in the FIFO.

Table 10-523. DSI VC TX FIFO Start Address

DSI_TX_FIFO_VC_SIZE.VCx_FIFO_ADD (where x = 0, 2)	Start Address
0	0
1	32
2	64
3	96
4	128

CAUTION

The different VC spaces must not overlap.

When the TX FIFO is full:

- The overflow interrupt (FIFO_TX_OVF_IRQ) is generated in the DSI_VC_IRQSTATUS_i[3] FIFO_TX_OVF_IRQ status bit.
- There is no L3_MAIN interconnect error generated.
- The interface commands are accepted but the data are not written into the FIFO.

To ensure that all writes are stored correctly in the TX FIFO, the FIFO must not be full. The room in the space allocated for the VC in the TX FIFO is given in the DSI_TX_FIFO_VC_EMPTINESS register. When no space is allocated in the TX FIFO for the VC, the DSI_TX_FIFO_VC_EMPTINESS register indicates a value of 0 for the VC space emptiness.

While waiting to receive the first VSYNC event on the video port to start video mode on the DSI link, no command data from TX FIFO is sent on the interface. This is required to ensure that when receiving the VSYNC event there is no ongoing command mode transfer that could delay the start of video mode on the DSI link.

10.3.4.4.3.2.2 DSI Command Mode RX FIFO

The RX FIFO stores the data received from the DSI PHY. The data are always packed in the RX FIFO (single or multiple packets received during single or multiple BTA periods).

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The read requests (single or burst) can be less than, equal to, or greater than the packet size. If the packet size is smaller than the read request, the following packet(s) is also transferred. If the packet size is longer than the read request, only part of the packet is transferred. In that case, the logic keeps the VC information to provide the rest of the data during the next read request(s).

The DSI_RX_FIFO_VC_SIZE register defines the allocated number of 33-bit values for each VC in the RX FIFO and the start address for each VC. Only the enabled VCs are considered.

To change the size of the memory space allocated for a specific VC, the VC must be disabled by resetting the DSI_VC_CTRL_i[0] VC_EN bit to 0. The entire FIFO cannot be used by the entire VC at the same time because a VC can be disabled to change one or multiple parameters. Software users must configure the start address and size for each VC correctly.

Table 10-524 lists the corresponding values for the size of the space allocated in the FIFO:

Table 10-524. DSI VC RX FIFO Size Values

DSI_RX_FIFO_VC_SIZE.VCi_FIFO_SIZE (where i = 0, 3)	Space Size (up to the size of the FIFO)
0	0 × 33 bits
1	32 × 33 bits
2	64 × 33 bits
3	96 × 33 bits
4	128 × 33 bits

NOTE: RX FIFO is 128 × 33 bits. Therefore, the sum of all VC FIFO allocations cannot exceed 128 × 33 bits.

CAUTION

Bit 32 of each location in the FIFO is used by the DSI protocol engine to tag the data in the RX FIFO. It is for internal use only.

Table 10-525 lists the start address of the space in the FIFO.

Table 10-525. DSI VC RX FIFO Start Address

DSI_RX_FIFO_VC_SIZE.VCx_FIFO_ADD (where x = 0, 2)	Start Address
0	0
1	32
2	64
3	96
4	128

CAUTION

The different VC spaces must not overlap.

While reading the received bytes in the RX FIFO, only the DSI_VC_SHORT_PACKET_HEADER_i register is used, because hardware does not keep track of the header position for long packets and the start/end of each packet. Software must extract the information from the bytes read from the RX FIFO. There is no specific hardware to track the received bytes in the RX FIFO. The DSI_VC_LONG_PACKET_HEADER_i and DSI_VC_LONG_PACKET_PAYLOAD_i registers are not used.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The ECC is used only by the first header when receiving multiple packets during the same LP RX transfer from the peripheral because the DSI protocol engine does not parse the header to identify the length of the packets. In case of multiple packets, the checksum is not enabled because hardware checks the checksum considering a single packet. The ECC in the first header is used to correct and check the header. For the following headers in the same LP RX transfer, hardware does not detect a header and cannot check and/or detect errors in the headers of the packets except for the first packet.

When the RX FIFO is empty:

- No interface error is generated.
- Commands are accepted and the data for the responses are 0s.

10.3.4.4.3.2.3 DSI Command Mode DMA Requests

The DMA requests (DSI_DMA_REQ) are used to allow automatic transfer by the DMA_SYSTEM or MPU (with less efficiency and throughput capability) from the DSI RX FIFO to the system memory and from the system memory to the DSI TX FIFO. Two independent DMA requests for RX FIFO and TX FIFO for the same VC are supported. The read and write accesses can use burst structure.

The thresholds used for requests for the TX FIFO and RX FIFO are programmable through the DSI_VC_CTRL_i[19:17] DMA_TX_THRESHOLD and DSI_VC_CTRL_i[26:24] DMA_RX_THRESHOLD bit fields for TX FIFO and RX FIFO, respectively. DMA requests are asserted on the threshold value. The size of the space allocated in TX FIFO for each VC must be a multiple of the value of the DSI_VC_CTRL_i[19:17] DMA_TX_THRESHOLD bit field.

In the case of TX FIFO, if all the bytes defined by the word count field in the DSI_VC_LONG_PACKET_HEADER_i register are received, the DMA request is no longer asserted. Even during the last transfer, less than the DMA_TX_THRESHOLD number of bytes are received because the word count is not a multiple of the DMA_TX_THRESHOLD value.

In the case of RX FIFO, while the DMA request is used to transfer the data from the RX FIFO to the system memory, the DMA_SYSTEM must be programmed to read the exact number of received bytes in the FIFO. If users do not know the size of the received bytes, the direct access of the RX FIFO through the DSI_VC_SHORT_PACKET_HEADER_i register is performed until the DSI_VC_CTRL_i[20] RX_FIFO_NOT_EMPTY bit goes to 0.

The only exception is when the LP data transfer finishes and the threshold value is not reached. In this case, the DMA request is asserted. The drain of the FIFO is supported in that configuration to empty the FIFO even if the number of data received is not a multiple of the threshold value.

The use of each DMA request is programmable by software. The DSI_VC_CTRL_i[23:21] DMA_TX_REQ_NB bit field is dedicated to DMA request numbering for the TX FIFO. The DSI_VC_CTRL_i[29:27] DMA_RX_REQ_NB bit field is dedicated to DMA request numbering for the RX FIFO.

When the DMA request is used to indicate the number of 32-bit values ready in the RX FIFO that BTA has received from the peripheral, which indicates an end of the transfer from the peripheral to the host for a transfer to the system memory, the DMA request that corresponds to the VC ID is generated.

The DMA_SYSTEM transfers the number of 32-bit values defined in the threshold register or the exact number of bytes received from the peripheral (the user must know the number of expected received bytes to program the DMA_SYSTEM correctly). When the DMA_SYSTEM transfers a multiple number of threshold values, the DSI protocol engine sends 0s for the data when there is no more received data in the RX FIFO for the VC. Software users must parse the data and determine the valid bytes.

The size of the DMA transfer can be determined by reading the DSI_RX_FIFO_VC_FULLNESS register. The BTA interrupt (BTA_IRQ) must be used to determine when to read the number of received bytes. The BTA interrupt must be monitored by reading the DSI_VC_IRQSTATUS_i[5] BTA_IRQ status bit. The DMA request must not be enabled until the DMA_SYSTEM is programmed with the correct number of data to read from RX FIFO.

This method must also be used when the RX FIFO space for the VC is expected to overflow because the expected number of data to be received is greater than the space allocated for the VC. Instead, the DMA request is asserted as soon as the threshold is reached or when BTA is received.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

When the DMA request is used to indicate the number of 33-bit entries empty in the TX FIFO for a transfer from the system memory, the DMA request corresponding to the VC ID is generated.

NOTE: For the most efficient transfer, the size of the request (read or write, single or burst) must be aligned with the threshold value.

Concurrent access using interlaced requests (read/write) to the TX and RX FIFO is supported for the same VC ID or different VC IDs.

10.3.4.4.3.3 DSI Video + Command Mode

The two modes can be interlaced to send two DSI streams to two types of panels: video and command. The number of concurrent video streams is limited to one. The number of concurrent command mode streams is limited to four when there is no video stream, and three when there is a video stream.

- For DSI1_A and DSI1_C, which have two video ports (see Section 10.3.4.4.5, *DSI Video Port Interface*), it is possible to send video or command mode streams from DISPC to DSI1_x primary video port (VP1), and a command stream on the secondary VP (VP2) for interleaving. In addition, it is also possible to send concurrently a command mode stream on the L3_MAIN Interconnect slave port for interleaving.

10.3.4.4.3.4 DSI Burst Mode

Frequency and transparent burst modes are supported:

- Frequency burst mode is used to reduce the HS period by increasing the clock frequency on the DSI link. In some cases, it reduces power consumption on the link. The non-HS period used typically to drive the main panel can be used to send data to the secondary panel or to allow feedback (acknowledge) from the primary and secondary panels. The DSI protocol engine must buffer a full line before sending the HS packets for the line. A double-buffering mechanism is required to send a line while the following one is being received on the video port. For more information about double-buffering, see Section 10.3.4.4.5.4, *Ping-Pong Buffer*.
- The transparent burst mode is used by increasing the pixel clock frequency generated by the DISPC with an increase of the horizontal blanking period.

10.3.4.4.3.5 DSI Interleaving Mode

Video mode can output command mode packets, which are provided to DSI through the L3_MAIN interconnect during the blanking periods of the video stream sequence on the PPI link. These command mode packets can be programmed as HS packets or low-power packets.

During a video stream sequence on the PPI link, four types of gap exist:

- BLLP gap: Blanking period during VSA, VBP, and VFP lines
- HSA gap: Blanking period during VACT lines; always between HS and HE short packet
- HBP gap: Blanking period during VACT lines; always between HS/HE short packet and data pixel long packet
- HFP gap: Blanking period during VACT lines; always between data pixel long packet and the end of the current VACT line

To perform interleaving in a particular gap, video mode must be set to go into LPS during the blanking gap. Each type of gap has separate configurable register bits that determine whether a blanking long packet will be sent or the link will go into LPS during the gap on the PPI link. If LPS is set during a gap, the DSI module performs interleaving during that period.

Two sets of registers are available for:

- HS interleaving (when HS command mode packets must be sent during a video stream on the PPI link)
- Low-power interleaving (when low-power command mode packets must be sent during a video stream on the PPI link)

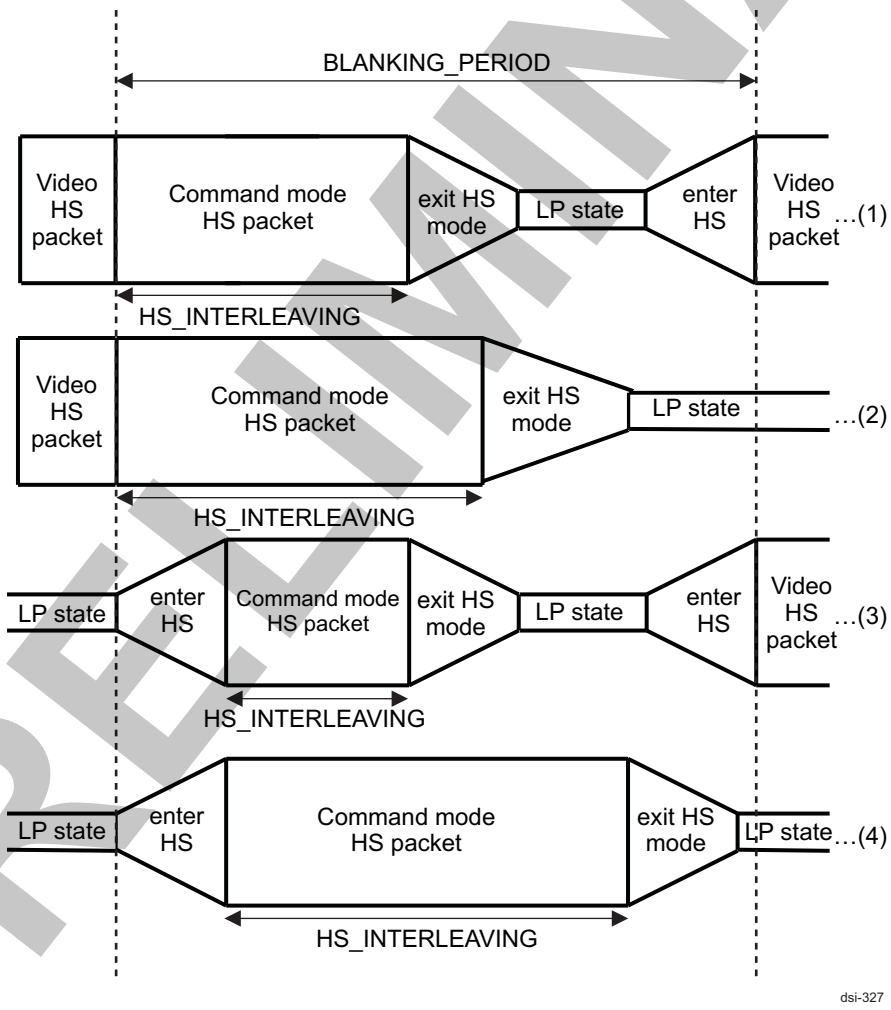
10.3.4.4.3.5.1 DSI HS Command Mode Interleaving

Figure 10-123 shows the various HS mode scenarios in interleaving mode during a blanking gap. For each type of blanking gap, a dedicated bit field determines the number of TXBYTECLKHS clock cycles used for interleaving in HS command mode packets.

- The DSI_VM_TIMING6[31:16] BL_HS_INTERLEAVING bit field defines the number of TXBYTECLKHS clock cycles used to interleave HS command mode packets during a BLLP gap.
- The DSI_VM_TIMING4[7:0] HBP_HS_INTERLEAVING bit field defines the number of TXBYTECLKHS clock cycles used to interleave HS command mode packets during an HBP gap.
- The DSI_VM_TIMING4[15:8] HFP_HS_INTERLEAVING bit field defines the number of TXBYTECLKHS clock cycles used to interleave HS command mode packets during an HFP gap.
- The DSI_VM_TIMING4[23:16] HSA_HS_INTERLEAVING bit field defines the number of TXBYTECLKHS clock cycles used to interleave HS command mode packets during an HSA gap.

These programmable values must be programmed to satisfy the timings for the clock and data lane to enter and exit HS mode latency. According to the scenario, different equations must be considered when calculating the register values.

Figure 10-123. DSI HS Command Mode Interleaving



NOTE: For calculations and equations, the following abbreviations are used: EXIT_CLK_HS_MODE represents the exit HS mode latency for the clock lane. There is no dedicated register for this value but the programmer must know this value for further calculations:

$$EXIT_CLK_HS_MODE = T_{CLK\text{-}TRAIL} + TH_{S\text{-}EXIT}$$

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: For more information about other timing parameters used in the following equations, see Section 10.3.4.4.4.1, *Timing Parameters for an LP-to-HS Transaction*, and Section 10.3.4.4.4.2, *Timing Parameters for an HS-to-LP Transaction*.

For the following equations, BLANKING_PERIOD represents the BLLP, HSA, HBP, or HFP blanking periods. The HS_INTERLEAVING period represents the maximal period HS command mode packets. Its value is set in the following bit fields, depending on the blanking type:

- BL_HS_INTERLEAVING
- HSA_HS_INTERLEAVING
- HBP_HS_INTERLEAVING
- HFP_HS_INTERLEAVING

In each scenario, two calculations are present, depending on the value of the DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit:

- DDR_CLK_ALWAYS_ON = 1: Clock lane is always active.
- DDR_CLK_ALWAYS_ON = 0: Clock lane is activated only when there are HS packets to be sent on the PPI link.

CAUTION

When the DDR_CLK_ALWAYS_ON bit is programmed to 1, the following must be considered:

- LPS can be achieved on the PPI link only if the data lane has enough time to go out from HS mode and enter a new HS mode during a period inside which the PPI link is meant to be in LPS. This can be expressed with the following equation:

  EXIT_HS_MODE_LATENCY + max{ENTER_HS_MODE_LATENCY, 2} + 1 ≤ BLANKING_PERIOD
- If the equation cannot be satisfied, because the LPs period is too short, software must program the DSI module in a way that during this blanking period a HS blanking packet is sent.

When the DDR_CLK_ALWAYS_ON bit is programmed to 0, the following must be considered:

- LPS can be achieved on the PPI link only if the data and clock lanes have enough time to go out from HS mode and enter a new HS mode during a period inside which the PPI link is meant to be in LPs. This can be expressed with the following equations:

  EXIT_HS_MODE_LATENCY + max{ENTER_HS_MODE_LATENCY, 2} + 1 ≤ BLANKING_PERIOD

  DDR_CLK_POST + EXIT_CLK_HS_MODE + DDR_CLK_PRE + ENTER_HS_MODE_LATENCY(data lane) + 1 ≤ BLANKING_PERIOD
- If both equations cannot be satisfied, because the LPS period is too short, software must program the DSI module in a way that during this blanking period a HS blanking packet is sent.

- Scenario 1: The gap for interleaving starts and ends with a regular video stream HS packet.
  - DDR_CLK_ALWAYS_ON = 1

    HS_INTERLEAVING = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY + max{ ENTER_HS_MODE_LATENCY, 2} + 1)
  - DDR_CLK_ALWAYS_ON = 0

    HS_INTER1 = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY + max{

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

ENTER_HS_MODE_LATENCY, 2} + 1)

HS_INTER2 = BLANKING_PERIOD – (DDR_CLK_POST + EXIT_CLK_HS_MODE + DDR_CLK_PRE + ENTER_HS_MODE_LATENCY + 1)

HS_INTERLEAVING = min{HS_INTER1, HS_INTER2}

- Scenario 2: The gap for interleaving starts with a regular video stream HS packet and ends in LPS.
  - DDR_CLK_ALWAYS_ON = 1

    HS_INTERLEAVING = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY + 3)
  - DDR_CLK_ALWAYS_ON = 0

    HS_INTER1 = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY + 3)

    HS_INTER1 = BLANKING_PERIOD – (DDR_CLK_POST + EXIT_CLK_HS_MODE + 3)

    HS_INTERLEAVING = min{HS_INTER1, HS_INTER2}
- Scenario 3: The gap for interleaving starts with LPS and ends with a regular video stream HS packet.
  - DDR_CLK_ALWAYS_ON = 1

    HS_INTERLEAVING = BLANKING_PERIOD – (ENTER_HS_MODE_LATENCY + EXIT_HS_MODE_LATENCY + max{ ENTER_HS_MODE_LATENCY, 2} + 1)
  - DDR_CLK_ALWAYS_ON = 0

    HS_INTER1 = BLANKING_PERIOD – (DDR_CLK_PRE + ENTER_HS_MODE_LATENCY + EXIT_HS_MODE_LATENCY + max{ENTER_HS_MODE_LATENCY, 2} + 1)

    HS_INTER2 = BLANKING_PERIOD – (DDR_CLK_PRE + ENTER_HS_MODE_LATENCY + DDR_CLK_POST + EXIT_CLK_HS_MODE + DDR_CLK_PRE+ ENTER_HS_MODE_LATENCY + 1)

    HS_INTERLEAVING = min{HS_INTER1, HS_INTER2}
- Scenario 4: The gap for interleaving starts with LPS and ends with a regular video stream HS packet.
  - DDR_CLK_ALWAYS_ON = 1

    HS_INTERLEAVING = BLANKING_PERIOD – (ENTER_HS_MODE_LATENCY + EXIT_HS_MODE_LATENCY + 3)
  - DDR_CLK_ALWAYS_ON = 0

    HS_INTER1 = BLANKING_PERIOD – (DDR_CLK_PRE + ENTER_HS_MODE_LATENCY + EXIT_HS_MODE_LATENCY + 3)

    HS_INTER2 = BLANKING_PERIOD – (DDR_CLK_PRE + ENTER_HS_MODE_LATENCY + DDR_CLK_POST + EXIT_CLK_HS_MODE + 1)

    HS_INTERLEAVING = min{HS_INTER1, HS_INTER2}

10.3.4.4.3.5.2 DSI LP Command Mode Interleaving

Figure 10-124 shows the various LP mode scenarios in interleaving mode during a blanking gap. For each type of blanking gap, a dedicated bit field determines the number of bytes of LP command mode packets that can be sent during a blanking period.

- The DSI_VM_TIMING6[15:0] BL_LP_INTERLEAVING bit field defines the number of bytes of LP command mode packets that can be sent during a BLLP gap.
- The DSI_VM_TIMING5[7:0] HBP_LP_INTERLEAVING bit field defines the number of bytes of LP command mode packets that can be sent during an HBP gap.
- The DSI_VM_TIMING5[15:8] HFP_LP_INTERLEAVING bit field defines the number of bytes of LP command mode packets that can be sent during an HFP gap.
- The DSI_VM_TIMING5[23:16] HSA_LP_INTERLEAVING bit field defines the number of bytes of LP command mode packets that can be sent during an HSA gap.

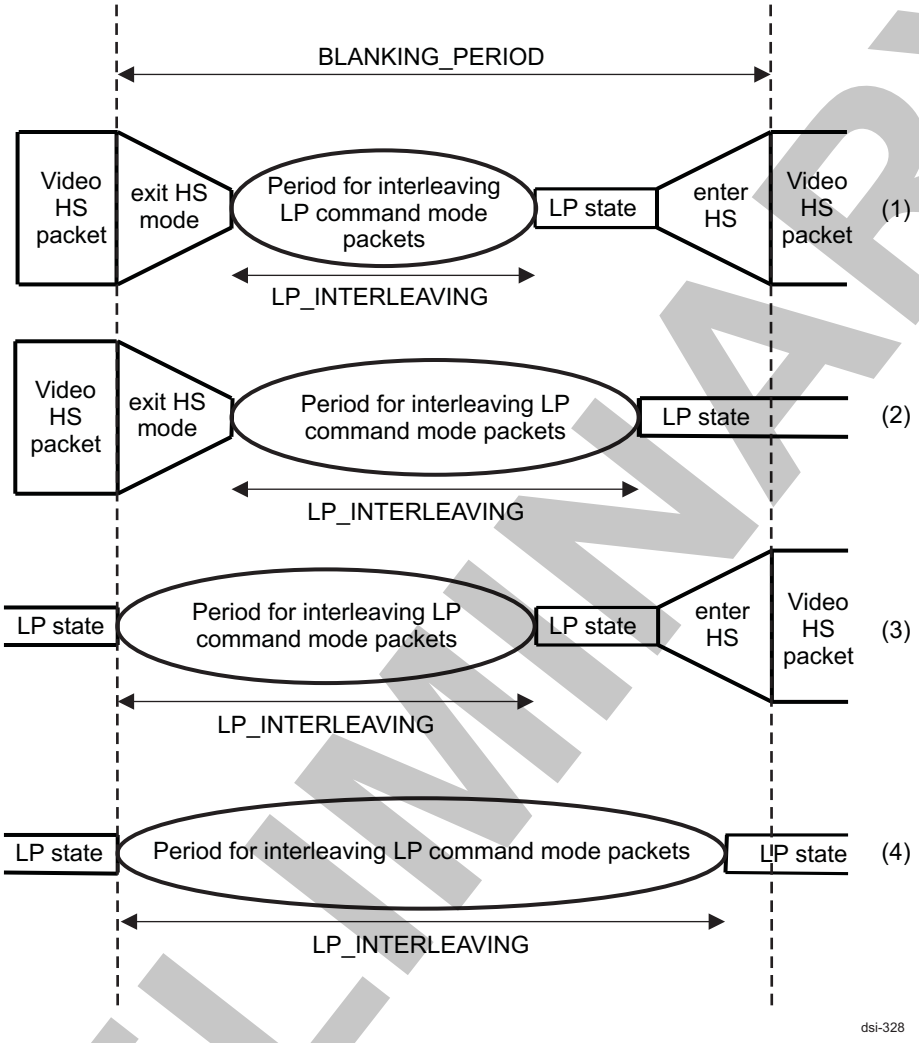
These values must be programmed to satisfy the timings for clock and data lane enter and exit LP mode latency. Clock lane timings do not affect LP command mode interleaving, because the clock lane can be controlled separately, compared with the data lane HS and low-power mutually exclusive control. Clock lanes can be in HS mode while the data lanes are in HS data transfer mode, low-power data transfer mode, or in LPS.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

According to this scenario, different equations must be considered to calculate register values.

Figure 10-124. DSI LP Command Mode Interleaving



For the following equations, BLANKING_PERIOD represents the BLLP, HSA, HBP, or HFP blanking periods. The LP_INTERLEAVING period represents the maximal period in LP command mode packets. Its value is set in the following bit fields, depending on the blanking type.

- BL_LP_INTERLEAVING
- HSA_LP_INTERLEAVING
- HBP_LP_INTERLEAVING
- HFP_LP_INTERLEAVING

ALLOWED_HSBYTE_CLOCKS_FOR_LP represents the number of TXBYTECLKHS clock cycles during which LP interleaving can appear.

To calculate the LP_INTERLEAVING value:

1. Calculate how many TXBYTECLKHS clock cycles can be reserved for LP interleaving during the appropriate blanking video mode gap.
2. Calculate the value of LP_INTERLEAVING according to the results of Step 1.

Step 1:

- Scenario 1: The gap for interleaving starts and ends with a regular video stream HS packet.

  ALLOWED_HSBYTE_CLOCKS_FOR_LP = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY +

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

max{ENTER_HS_MODE_LATENCY, 2} + 1)

- Scenario 2: The gap for interleaving starts with a regular video stream HS packet and ends in LPS.
  ALLOWED_HSBYTE_CLOCKS_FOR_LP = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY + 1)
- Scenario 3: The gap for interleaving starts with the LPS and ends with a regular video stream HS packet.
  ALLOWED_HSBYTE_CLOCKS_FOR_LP = BLANKING_PERIOD – (max{ENTER_HS_MODE_LATENCY, 2} + 1)
- Scenario 4: The gap for interleaving starts with LPS and ends with a regular video stream HS packet.
  ALLOWED_HSBYTE_CLOCKS_FOR_LP = BLANKING_PERIOD – 1

After finishing Step 1, the time period available for LP interleaving is known:

$T_{lp_available}$ = ALLOWED_HSBYTE_CLOCKS_FOR_LP *T TXBYTECLKHS

Step 2:

The resulting value must be programmed in the appropriate video mode register for LP interleaving.

$$LP_INTERLEAVING < \left[\frac{\frac{Tlp_available - 8*Thsbyte_clk - 5*Tdsif_clk}{Ttxclkesc}}{16} - 26 \right]$$

dsi-E124

Thsbyte_clk: Period of TXBYTECLKHS clock of the DSI_PHY_DSS_x module

Tdsif_clk: Period of DSI functional clock

Ttxclkesc: Period of LP transmit escape clock

10.3.4.4.4 DSI Clock Requirements

The serial clock generated by the DSI host and sent to the display can be a continuous clock. The clock lane supports clock transmission even if there is no data to send for displays that require continuous clock. It is software-programmed through the DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit: This bit can be programmed only when the interface is disabled (the DSI_CTRL[0] IF_EN bit set to 0).

The peripheral can use two different kinds of clocks. The first is the DDR clock provided on the clock lane. The second clock is some transitions on the first data lane even if there is no valid data to send using LP mode.

The LP clock (TxClkEsc) frequency provided to the DSI PHY is from 67 percent to 150 percent of the peripheral low-power (LP) clock frequency. It is generated internally by the DSI protocol engine module using the DSI functional clock. The DSI functional clock is divided by 1, 2, 3, up to 8191 using the value programmed in the DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR bit field. The LP clock generated from the DSI functional clock must be from 20 MHz to 32 kHz. The duty cycle must be 50/50 (minimum high time = 24 ns). LP clock frequency visible on the pads (DP x or DN) is half the frequency of TxClkEsc.

The DSI_CLK_CTRL[20] LP_CLK_ENABLE bit is used to enable or disable the clock. When disabled, the value of the DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR bit field is ignored and does not have to be programmed by software users.

10.3.4.4.4.1 DSI Timing Parameters for an LP-to-HS Transaction

Figure 10-125 shows the timing requirement when switching the data and clock lane state from LP to HS. Table 10-526 lists the LP to HS timing parameters.

Table 10-526. DSI LP-to-HS Timing Parameters

Timings	Description	Registers/Associated Bit Fields	Register Settings	Timing Seen on the Line
T_{LPX}	Length of any low-power state period	DSI_PHY_REGISTER1[20:16] REG_TLPXBY2 The value set in this bit field is half of the T_{LPX}	CEIL (25 ns / DDR_Clock_Period)	CEIL (2 * REG_TLPXBY2/4) * 4 * DDR_Clock_Period
$T_{CLK-PREPARE}$	Time to drive the CLK lane to LP-00 state, to prepare for HS clock transmission	DSI_PHY_REGISTER2[7:0] REG_TCLKPREPARE	CEIL (65 ns / DDR_Clock_Period)	REG_TCLKPREPARE * DDR_Clock_Period + (~–25– + 5 ns)
$T_{CLK-ZERO}$	Time to drive the CLK lane to HS-0 state, before starting the clock	DSI_PHY_REGISTER1[7:0] REG_TCLKZERO	CEIL (265 ns / DDR_Clock_Period)	{CEIL [(REG_TCLKZERO + 3)/4] * 4 + CEIL (REG_TCLKPREPARE/ 4) * 4 – REG_TCLKPREPARE + 2} * DDR_Clock_Period + (~ 0–+ 5 ns)
$T_{CLK-PRE}$	Time that the HS clock must be driven before any associated data lane begins the transition from LP to HS mode	N/A	N/A	DDR_CLK_PRE - T_{LPX} - $T_{CLK-PREPARE}$ - $T_{CLK-ZERO}$
$T_{HS-PREPARE}$	Time to drive the data lane to LP-00 state, to prepare for HS packet transmission	DSI_PHY_REGISTER0[31:24] REG_THSPREPARE	CEIL (70 ns / DDR_Clock_Period) + 2	REG_THSPREPARE * DDR_Clock_Period + (–26.5–+ 4 ns)
$T_{HS-ZERO}$ + $T_{HS-PREPARE}$	$T_{HS-ZERO}$: Time to drive the data lane to HS-0 state before the synchronous sequence	DSI_PHY_REGISTER0[23:16] REG_THSPRPR_THSZERO	CEIL (175 ns / DDR_Clock_Period) + 2	{CEIL [(N + 3)/4] * 4 + CEIL (M/4) * 4 + 3} * DDR_Clock_Period + (~ –29–0 ns). Where: N = REG_THSPREPARE_THSZERO – REG_THSPREPARE M = REG_THSPREPARE
$T_{DDR_CLK_PRE}$	Time between the CLK lane request assertion and the data request assertion to switch the data lanes to HS	DSI_CLK_TIMING[15:8] DDR_CLK_PRE	CEIL [(T_{LPX} + $T_{CLK-PREPARE}$ + $T_{CLK-ZERO}$ + $T_{CLK-PRE}$) / $T_{TXBYTECLKHS}$] (1) (2)	
$T_{ENTER_HS_MODE_LATENCY}$ (3)	Time to enter data lane into HS mode	DSI_VM_TIMING7[31:16] ENTER_HS_MODE_LATENCY	CEIL [(T_{LPX} + $T_{HS-PREPARE}$ + $T_{HS-ZERO}$) / $T_{TXBYTECLKHS}$] (1)	

(1) The timings seen on the line should be used to determine the register value.
(2) See the MIPI D-PHY specification for the $T_{CLK-PRE}$ value.
(3) ENTER_HS_MODE_LATENCY timing applies only to video mode. It does not need to be programmed in command mode.

In the example in Table 10-527, the DDR clock = 400 MHz; TxByteClkHS = 100 MHz.

Table 10-527. DSI LP-to-HS Timing Parameters Example for 400-MHz DDR Clock

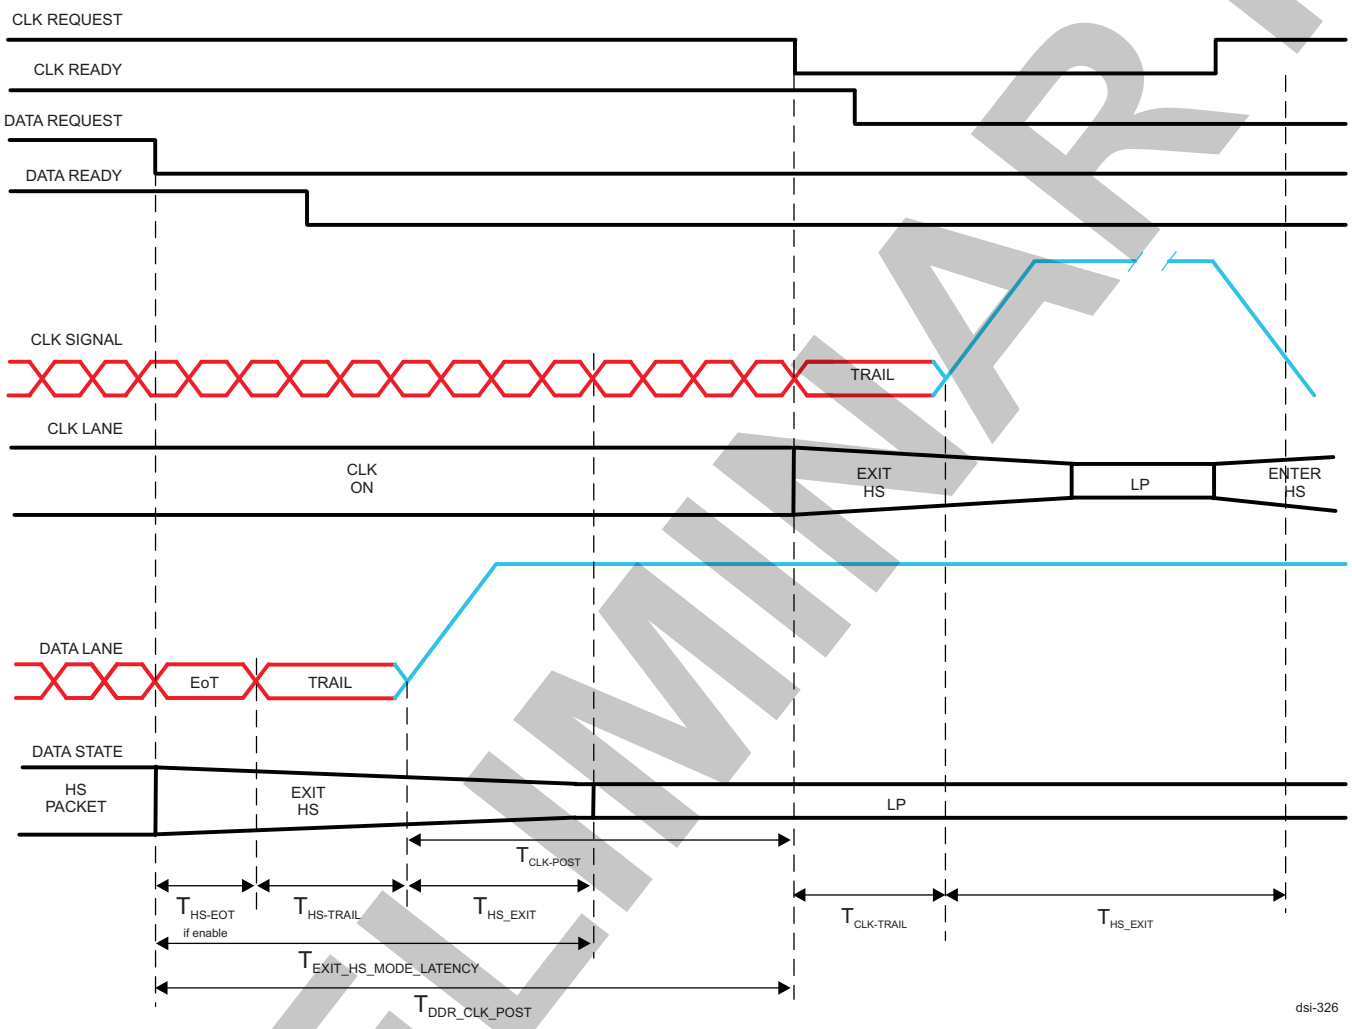
10.3.4.4.4.2 DSI Timing Parameters for an HS-to-LP Transaction

Figure 10-126 shows the timing requirement when switching the state of the data and clock lanes from HS to LP. Table 10-528 lists the HS-to-LP timing parameters.

Figure 10-126. DSI HS-to-LP Timing



PRELIMINARY

Table 10-528. DSI HS-to-LP Timing Parameters

Timings	Description	Registers/Associated Bit Fields	Register Settings	Timing Seen on the Line
T_{HS-EOT}	If EoT is enabled, a delay is added to EXIT_HS_MODE_LATENCY to send the EoT packet. The EoT period depends on the number of data lanes.	N/A	N/A	DIVROUNDUP (4, NB_DATA_LANES) Thus: One data lane = Four DDR clocks Two data lanes = Two DDR clocks
$T_{HS-TRAIL}$	Time to drive flipped differential state after last payload data bit of an HS transmission burst	DSI_PHY_REGISTER0[15:8] REG_THSTRAIL	CEIL (60 ns / DDR_Clock_Period) + 5	{CEIL [(REG_THSTRAIL + 3)/4] * 4 – 2.75} * DDR_Clock_Period + (~ 0– 5 ns)
$T_{HS-EXIT}$	Time to drive data lane to LP-11 state, after HS burst	DSI_PHY_REGISTER0[7:0] REG_THSEXIT	CEIL (145 ns / DDR_Clock_Period)	[CEIL (REG_THSEXIT/4) * 4] * DDR_Clock_Period – (~ 3–45 ns)
$T_{CLK-POST}$	Time that the transmitter must continue sending HS clock after the last associated data lane has transitioned to LP mode	N/A	N/A	DDR_CLK_POST - T_{HS-EOT} (1) - $T_{HS-TRAIL}$
$T_{CLK-TRAIL}$	Time to drive HS differential state after last payload clock bit of an HS transmission burst	DSI_PHY_REGISTER1[15:8] REG_TCLKTRAIL	CEIL (60 ns / DDR_Clock_Period) + 2	{CEIL [(REG_TCLKTRAIL + 3)/4] * 4 – 1.5} * DDR_Clock_Period + (~ 0– 5 ns)
$T_{DDR_CLK_POST}$	Time between the data lane request deassertion and the CLK request deassertion to switch the data lanes into LP mode. The DDR_CLK_POST value must follow the rule: DDR_CLK_POST ≥ $T_{HS-TRAIL}$ + T_{HS-EOT} + $T_{CLK-POST}$	DSI_CLK_TIMING[7:0] $T_{DDR_CLK_POST}$	CEIL [($T_{HS-TRAIL}$ + T_{HS-EOT} (1) + $T_{CLK-POST}$) / $T_{TXBYTECLKHS}$] (2) (3)	
$T_{EXIT_HS_MODE_LATENCY}$ (4)	Time to exit HS mode	DSI_VM_TIMING7[15:0] EXIT_HS_MODE_LATENCY	CEIL [($T_{HS-TRAIL}$ + $T_{HS-EXIT}$ + T_{HS-EOT} (1)) / $T_{TXBYTECLKHS}$] (2)	

(1) If T_{HS-EOT} is enabled
(2) The timings seen on the line should be used to determine the register value.
(3) See the MIPI D-PHY specification for the$T_{CLK-POST}$ value.
(4) EXIT_HS_MODE_LATENCY timing applies only to video mode. It does not need to be programmed in command mode.

In the example in Table 10-529, the DDR clock = 400 MHz; TxByteClkHS = 100 MHz; two data lanes.

Table 10-529. DSI HS to LP Timing Parameters Example for 400-MHz DDR Clock and Two Data Lanes

Timings	Registers/Associated Bit Fields	Default Register Settings (Programmed at Reset)	Timing Seen on the Line (T_{HS-EOT} Enabled)	Timing Seen on the Line (T_{HS-EOT} Disabled)
T_{HS-EOT}	N/A	N/A	5 ns	N/A
$T_{HS-TRAIL}$	DSI_PHY_REGISTER0 [15:8] REG_THSTRAIL	29	73.125–78.125 ns	73.125–78.125 ns

10.3.4.4.4.3 DSI Extra LP Transitions

Some DSI receivers require extra clock cycles in LP mode to process the data. The DSI protocol engine can be programmed to send automatically one NULL long packet. It applies only when no more data are ready to be sent from the internal FIFO to the peripheral on the last LS transfer. The same value is used for all the VCs sending packets in LS mode.

The size of the payload is defined by the DSI_CLK_CTRL[17:16] LP_CLK_NULL_PACKET_SIZE bit field. The header value depends on the size of the payload as described in Table 10-530 and Table 10-531.

NOTE: In Table 10-530 and Table 10-531, ECC and checksum are enabled.

Table 10-530. DSI Extra NULL PH

VC ID	Payload Size (DSI_CLK_CTRL[17:16] LP_CLK_NULL_ PACKET_SIZE)	Header (1st Byte)	Header (2nd Byte): WC LSB	Header (3rd Byte): WC MSB	Header (ECC)

10.3.4.4.5 DSI Video Port Interface

NOTE: The signals described in this section are internal and not bounded outside the device. This section describes the internal connections between the DISPC and the DSI protocol engine.

Table 10-532 and Table 10-533 summarize the video interface signals. DSI1_A and DSI1_C have two video ports (VP1 and VP2). These interfaces connect the DISPC outputs to the DSI protocol engine to send real-time data streams. For video mode, only the active matrix timings are supported by the DSI protocol engine.

- DSI1_A has two video ports (VP1 and VP2)
  - VP1 is connected to the LCD1 output of DISPC.
  - VP2 is connected to the LCD2 output of DISPC.
- DSI1_C has two video ports (VP1 and VP2)
  - VP1 is connected to the LCD1 output of DISPC.
  - VP2 is connected to the LCD3 output of DISPC.

Table 10-532. DSI Video Port 1 Signals for DSI1_A and DSI1_C Protocol Engines

Signal Name	Type(1)	Description
VP1_HSYNC	I	Horizontal synchronization signal
VP1_VSYNC	I	Vertical synchronization signal
VP1_DATA[23:0]	I	Parallel output data: Bits [23:0]
VP1_PCLK	I	Pixel clock. In case of STALL configuration, it is used to indicate when new data is on the data bus during the clock period of VP1_CLK. The VP1_PCLK is generated from VP1_CLK through division inside the DISPC. The clock ratio is indicated in the DSI_CTRL[4] VP_CLK_RATIO bit and must be aligned with the configuration of the clock divisor in the display controller (DISPC_DIVISOR1[7:0] PCD bit field for DISPC LCD1 output, and the DISPC_DIVISOR2[7:0] PCD bit field for DISPC LCD2 output). The source of the VP1_PCLK for DSI1_A is the DSS_DISPC_LCD1_PCLK. The source of the VP1_PCLK for DSI1_C is DSS_DISPC_LCD3_PCLK. For more information, see DISPC Clock Configurationin *Display Controller*, and , *DSI Clock Configuration*.
VP1_DE	I	Data enable
VP1_STALL	O	The STALL signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the DISPC is configured in stall mode; in that mode, HSYNC and VSYNC are not generated.)

(1) I = Input; O = Output

Table 10-532. DSI Video Port 1 Signals for DSI1_A and DSI1_C Protocol Engines (continued)

Signal Name	Type[1]	Description
VP1_CLK	I	DISPC internal clock. It is a free-running clock. The source of VP1_CLK for DSI1_A is LCD1_CLK, divided down. The source of VP1_CLK for DSI1_C is LCD3_CLK, divided down. For more information, see DISPC Clock Configurationin *Display Controller*, and , *DSI Clock Configuration*

Table 10-533. DSI Video Port 2 Signals for DSI1_A and DSI1_C Protocol Engines

Signal Name	Type[1]	Description
VP2_HSYNC	I	Horizontal synchronization signal
VP2_VSYNC	I	Vertical synchronization signal
VP2_DATA[23:0]	I	Parallel output data: Bits [23:0]
VP2_PCLK	I	Pixel clock. In case of STALL configuration, it is used to indicate when new data is on the data bus during the clock period of VP2_CLK. The VP2_PCLK is generated from VP2_CLK through division inside the DISPC. The clock ratio is indicated in the DSI_CTRL2[4] VP_CLK_RATIO bit and must be aligned with the configuration of the clock divisor in the display controller (DISPC_DIVISOR2[7:0] PCD bit field for DISPC LCD2 output). The source of the VP2_PCLK for DSI1_A is the DSS_DISPC_LCD2_PCLK. The source of the VP2_PCLK for DSI1_C is LCD1_PCLK. For more information, see DISPC Clock Configuration in *Display Controller*, and , *DSI Clock Configuration*.
VP2_DE	I	Data enable
VP2_STALL	O	The STALL signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the DISPC is configured in stall mode; in that mode, HSYNC and VSYNC are not generated.)
VP2_CLK	I	DISPC internal clock. It is a free-running clock. The source of the VP2_CLK for DSI1_A is LCD2_CLK, divided down. The source of the VP2_CLK for DSI1_C is LCD1_CLK, divided down. For more information, see DISPC Clock Configuration in *Display Controller*, and , *DSI Clock Configuration*.

(1) I = Input; O = Output

NOTE:

- The polarities of VP_HSYNC and VP_VSYNC are programmable by setting the DSI_CTRL and DSI_CTRL2 registers.
- Clocks VP_CLK and VP_PCLK can have the same frequency.
- The number of bits to be captured on the video port (the width of the data bus) is defined in the DSI_CTRL[7:6] VP_DATA_BUS_WIDTH bit field.
- For the 18-bit pixel format using 24 bits on the DSI link, the format to be used by the DSI protocol engine is 24-bit, because the DISPC must convert the 18-bit pixels into 24-bit pixels. There is no logic inside the DSI protocol engine to convert from 18-bit format to 24-bit format.

The data received on the video port can be stored in the line buffer memories or sent directly on the DSI interface in two cases:

- The line buffer size is too small compared to the line from the DISPC.
- There is no line buffer instantiated. If there is no line buffer, the burst mode, defined as frequency burst mode, cannot be used. Only transparency burst mode is supported.

NOTE: The DSI_CTRL[13:12] LINE_BUFFER and DSI_CTRL2[13:12] LINE_BUFFER bit fields define the number of lines to be used for transferring data from the video port to the DSI1_A and DSI1_C links.

10.3.4.4.5.1 DSI Video Port Used for Video Mode

If the video port is used for video mode, VP_STALL is not used. Table 10-534 and Table 10-535 list the active signals on the video port.

VP2_DATA[23:0]	I	Parallel output data: Bits [23:0]
VP2_PCLK	I	Pixel clock
VP2_DE	I	Data enable
VP2_CLK	I	A free-running clock used as the DISPC functional clock

(1) I = Input; O = Output

Three video modes are available:

- No-line buffer: The data received on the video port are directly output to the DSI port without buffering. The ratio of VP_PCLK and the DSI HS clock period must ensure the same throughput on the two ports (the two clocks must be generated using the same PLL; the subsystem must provide this configuration).
- One-line buffer:
  - The data can be transferred as described in the no-line buffer configuration.
  - The data are first stored in the line buffer; and then when all the data for one line are received, the DSI protocol engine sends the entire line. Software must adjust timings to let enough time for storing all line data into the line buffer before sending to DSI outputs. The synchronization packets are never stored in the line buffer.
- Two-line buffers:
  - The data can be transferred as described in the one-line buffer configuration.
  - One line is stored when the second line is output on the DSI port. This allows burst capability. While receiving the first line of the frame, no RGB packets are sent, because the line buffers are empty. To send the last line of the frame, a dummy line must be provided by the display controller to flush the line buffers. The synchronization packets are never stored in the line buffer.

NOTE: If more active lines are received on the video port than the number of lines defined in the DSI_VM_TIMING3[15:0] VACT bit field, the extra lines are discarded by the DSI protocol engine. These lines are treated as blanking lines.

Figure 10-127 through Figure 10-129 show these three video modes.

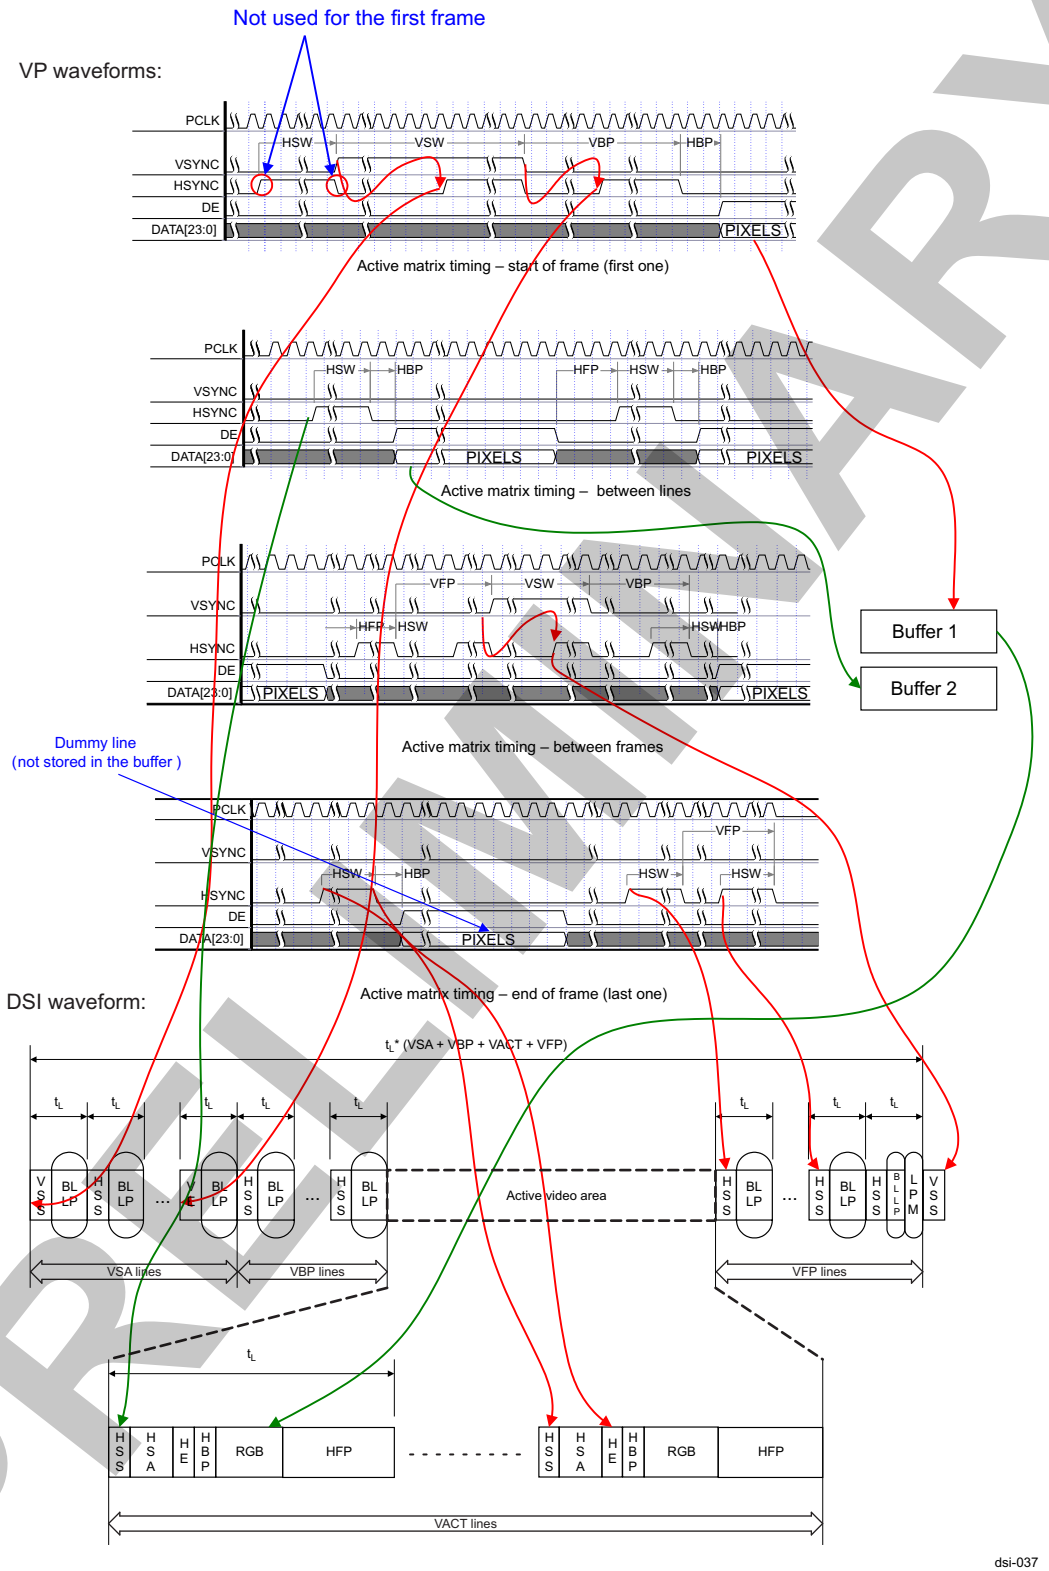
Figure 10-129. DSI Video Mode With Burst (Two-Line Buffers)



PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: In Figure 10-127 through Figure 10-129:

- When HSYNC start and HSYNC end short packets are not generated (HSA does not exist), the HBP signal must not be 0.
- Software must ensure that VBP is always defined so that there is at least one HSYNC during VBP.
- In blanking low-power mode (BL-LP), two options are possible:
  - The lane remains in ULPS, and the DSI_CTRL[20] BLANKING_MODE bit is set to 0x0.
  - Dummy bytes are sent during LP with the DSI_CTRL[20] BLANKING_MODE bit set to 0x1; the number of sent bytes is determined by the DSI_VM_TIMING6[15:0] BL_LP_INTERLEAVING bit field.

In DSI video mode, if the VSA bit field in DSI_VM_TIMING2 is set to 0x0, no vertical synchronization packet will be sent, even if VP_VSYNC_START is set to 0x1 in DSI_CTRL.

If the VP_DE signal is not asserted during enough VP_PCLK cycles to be able to capture the number of bytes defined in the word count of the header, the module must send the valid data received on the video port followed by bytes of 0s to match the required number of bytes to transmit. The VP_PCLK must be present during all extra cycles where the DSI protocol engine is expecting pixels.

If the VP_DE signal is asserted for too many VP_PCLK cycles, the module stops capturing the data on the video port while the number of bytes to capture, as defined in the word count field of the header, is reached.

The HS checks that the received synchronization events on the video port (VSYNC and HSYNC) are within the synchronization window based on expected timings. If the timings (internal and received) are out of sync, the interrupt for out-of-sync is generated and the interface is disabled (the DSI_CTRL[0] IF_EN bit is automatically reset by hardware). The unsynchronization window is defined by the DSI_VM_TIMING2[27:24] WINDOW_SYNC bit field.

10.3.4.4.5.2 DSI Video Port Used for Command Mode

If the video port is used for command mode, the VP_HSYNC, VP_VSYNC, and VP_DE signals are not used. Table 10-536 and Table 10-537 describe the active signals on video port 1 and video port 2, respectively.

Table 10-536. DSI Video Port 1 for DSI1_A and DSI1_C in the Context of Command Mode

Signal Name	Type(1)	Description
VP1_DATA[23:0]	I	Parallel output data: Bits [23:0]
VP1_PCLK	I	One pulse is generated every time new data is output on the data bus.
VP1_STALL	O	The STALL signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the DISPC is configured in stall mode; in that mode, HSYNC and VSYNC are not generated.)
VP1_CLK	I	DISPC internal clock. A free-running clock used as the DISPC functional clock.

(1) I = Input; O = Output

Table 10-537. DSI Video Port 2 for DSI1_A and DSI1_C in the Context of Command Mode

Signal Name	Type(1)	Description
VP2_DATA[23:0]	I	Parallel output data: Bits [23:0]
VP2_PCLK	I	One pulse is generated every time new data is output on the data bus.
VP2_STALL	O	The STALL signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the DISPC is configured in stall mode; in that mode, HSYNC and VSYNC are not generated.)
VP2_CLK	I	DISPC internal clock. A free running-clock used as the DISPC functional clock.

(1) I = Input; O = Output

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: The STALL signal must be deasserted to receive pixels and asserted to stop receiving pixels.

Figure 10-130 and Figure 10-131 show the VP_STALL signal assertion and deassertion on rising and falling edges, respectively.

Figure 10-130. DSI Stall Timing With Pixel on Rising Edge

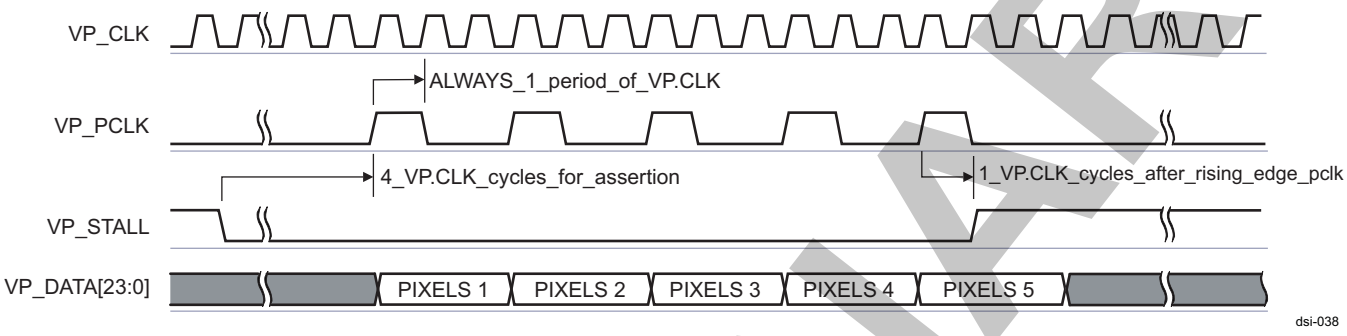


Figure 10-131. DSI Stall Timing With Pixel on Falling Edge

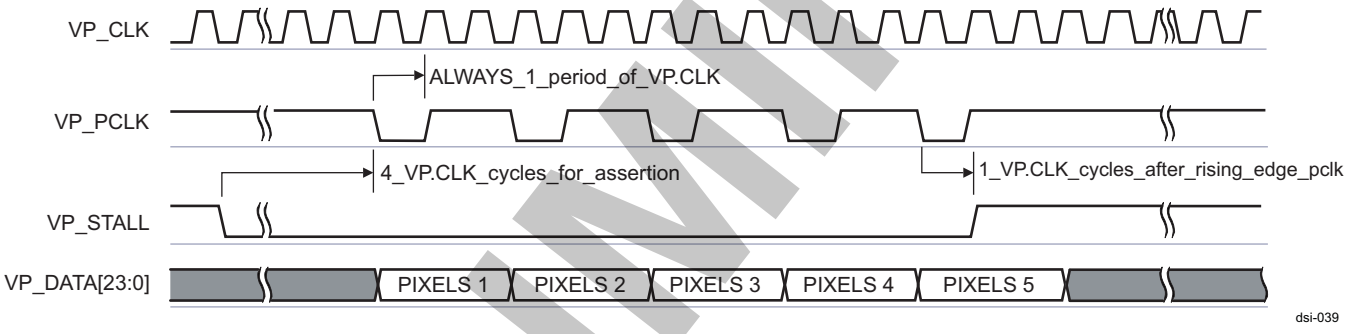


The VP_STALL signal is asserted to stop the transfer when the last data is output. The data can be output on the rising or falling edge of the VP_PCLK through registers in the DISPC. Data output on the falling edge of VP_PCLK is supported by the DSI protocol engine.

The VP_PCLK clock is generated from VP_CLK; these two clocks are balanced. Assertion and deassertion of VP_PCLK is done on the rising edge of VP_CLK. The width of the VP_PCLK pulse depends on the configuration of the clock divisor in the DISPC. For more information, see DISPC Overview, in *Display Controller*. In the DSI protocol engine, the information is defined in the DSI_CTRL[4] VP_CLK_RATIO bit and must be aligned with the DISPC configuration.

Deassertion of the VP_STALL signal occurs at least four VP_CLK cycles before assertion of VP_PCLK. Assertion of VP_STALL occurs one cycle VP_CLK after deassertion of VP_PCLK for the last pixel to be transferred. The VP_CLK clock is generated by the DISPC under software control. It can be kept running between assertion and deassertion of VP_STALL.

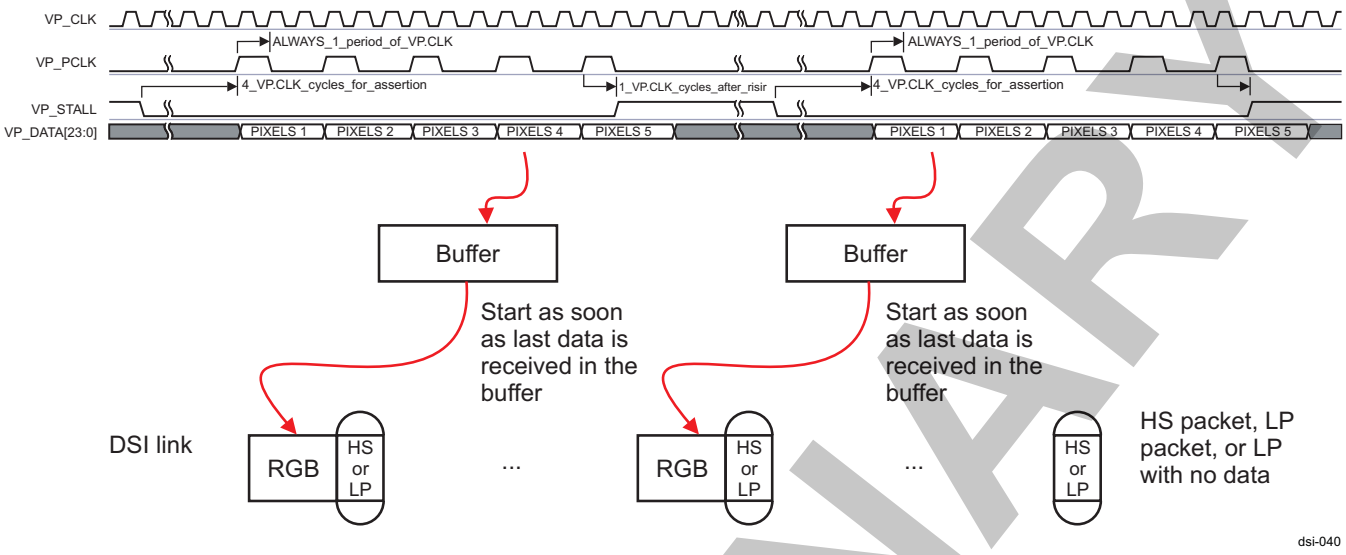
The stall assertion/deassertion depends on the number of bytes to be received considering the size of the video port bus defined in the DSI_CTRL[7:6] VP_DATA_BUS_WIDTH bit field for video port 1 and the DSI_CTRL2[7:6] VP_DATA_BUS_WIDTH bit field for video port 2.

Figure 10-132 shows the data flow in command mode using the video port.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-132. DSI Data Flow in Command Mode Using the Video Port



Two command modes are available:

- One-line buffer: The data are stored in the line buffer before being sent.
- Two-line buffers: The two lines are used if the word count defined in the DSI_VC_LONG_PACKET_HEADER_i register is bigger than the line size; otherwise, one-line buffer must be used.

NOTE: In command mode, the video port can be used only in one- or two-line buffer configuration. No-line buffer configuration is not allowed.

The packets can be sent using high speed or low speed.

The DCS command in the payload can be inserted automatically using the DSI_VC_CTRL_i[30] DCS_CMD_ENABLE bit. If TE is used, hardware automatically inserts the DCS Write Start command for the first packet of the frame transfer and th DCS Write Continue command for all subsequent packets. The DSI_VC_CTRL_i[31] DCS_CMD_CODE bit is ignored.

10.3.4.4.5.3 DSI Burst Mode

When burst mode is enabled, the video port receives data from the DISPC at the pixel clock. The DSI protocol engine buffers the data in its own line FIFO (double-line buffer size). The read speed of the line can be twice the pixel clock to increase the blanking time of the video mode and to allow command mode traffic to be interleaved during the blanking period. Burst mode uses a dual-line buffer.

The DSI port can output data from one line buffer while the second line buffer is accessed by the video port. The two processes are concurrent but they do not access the same line at the same time. The DSI transfer can start only when the entire video port line is transferred into a line buffer. The switch is controlled by the VP_HS signal on the video port side and by an internal signal on the DSI port indicating that the last data for the current line has been written into the line buffer.

NOTE: The line buffers are used to store only the pixels. The synchronization codes are not stored in the line buffers; they must be sent according to the video port timings.

NOTE: The number of line buffers to be used while receiving data on the video port can be selected by setting the DSI_CTRL[13:12] LINE_BUFFER bit field.

PRELIMINARY

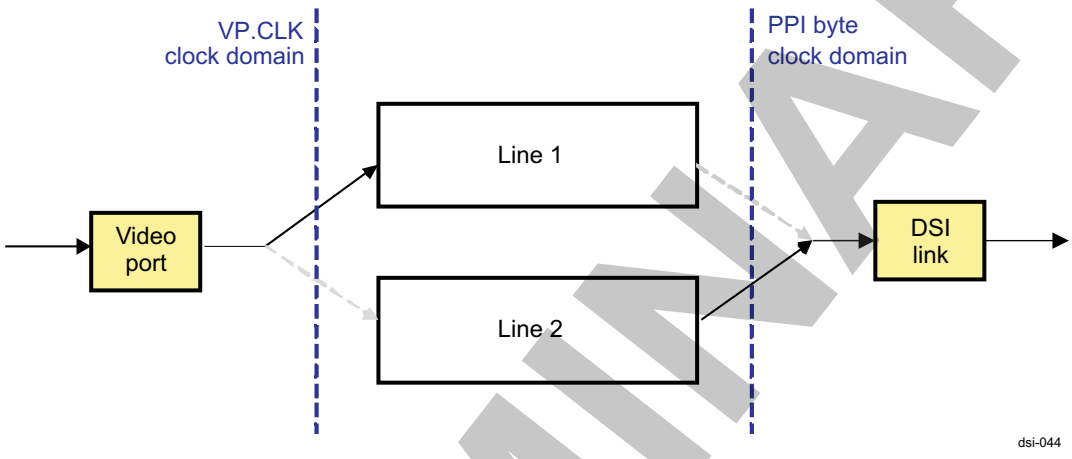
10.3.4.4.5.4 DSI Ping-Pong Buffer

The ping-pong buffer stores data incoming from the DISPC in one of the two line buffers. When one line buffer is used to store the pixels received on the video port, the other line buffer is used to provide data on the DSI link. The ping-pong buffer is supported in command mode, provided the size of the packet defined in the header register is less than the size of each line buffer (768 × 32 bits for VP2 of DSI1_A and DSI1_C, and 960 × 32 bits for VP1 of DSI1_A and DSI1_C). If the size of the packet is greater than the size of the line buffer, the ping-pong mechanism cannot be used (both lines are used as a single line).

Figure 10-133 shows the video port used in ping-pong mode .

Figure 10-133. DSI Ping-Pong Mode



The ping-pong buffer status can be checked by the DSI_VC_CTRL_i[14] PP_BUSY bit.

- When PP_BUSY equals 1, the ping-pong buffer is active and the line buffers are not ready to receive data; therefore, a new header cannot be updated.
- When PP_BUSY equals 0, at least one line buffer is empty; therefore, a new header can be updated. PP_BUSY is then set to 0x1. If both line buffers are empty, two headers can be written, one following the other. PP_BUSY remains at 0x0 after the first header is written, and is set to 0x1 after the second header is written.

An IRQ is available to update header on events. The IRQ is enabled by setting the DSI_VC_IRQENABLE_i[8] PP_BUSY_CHANGE_IRQ bit to 0x1, and its status is accessible on the DSI_VC_IRQSTATUS_i[8] PP_BUSY_CHANGE_IRQ bit.

10.3.4.4.6 DSI SCP Interface

The SCP interface is used to transfer register values from the DSI protocol engine to the DSI PLL control module and to the DSI PHY. It spends several cycles to serialize the data to be sent. Software users must consider the delay in processing the transfer of the data from/to the L3_MAIN interconnect slave port to/from the module.

10.3.4.4.6.1 DSI Shadowing Register

The first three SCP registers for the DSI PHY address map must be implemented as shadow registers. The shadowing mechanism is enabled and disabled using the DSI_COMPLEXIO_CFG1[31] SHADOWING bit:

- When setting the DSI_COMPLEXIO_CFG1[31] SHADOWING bit to 1, the transfer of the values from the three first local interconnect port registers into the first three registers of the DSI PHY (DSI_PHY_REGISTER0 through DSI_PHY_REGISTER2) is done only when the DISPC_UPDATE_SYNC signal from the DISPC is active and the DSI_COMPLEXIO_CFG1[30] GOBIT bit is set to 1. If there is no pending update for the three registers when the DISPC_UPDATE_SYNC signal is asserted, the DSI_COMPLEXIO_CFG1[30] GOBIT bit is reset by hardware and there is no SCP transfer.
  - If only one register needs to be updated, only the corresponding new value is transferred. The

Copyright © 2013, Texas Instruments Incorporated
PRELIMINARY

second and third registers in the DSI PHY are not updated. When the transfer completes, the DSI_COMPLEXIO_CFG1[30] GOBIT bit is reset by hardware.

– If two registers need to be updated, the register with the lower address is transferred first, followed by the second register. When the transfers complete, the DSI_COMPLEXIO_CFG1[30] GOBIT bit is reset by hardware.

– If three registers need to be updated, the register with the lowest address is transferred first, and then the other registers are transferred according to incremental address. When the transfers complete, the GOBIT bit is reset by hardware.

When there is an ongoing transfer (read or write) to any SCP register, the transfer must complete before updating the shadowing registers.

- When setting the DSI_COMPLEXIO_CFG1[31] SHADOWING bit to 0, if the transfer into the first two DSI PHY registers has already started, it should be finished.

NOTE: When reading the shadow registers, the local value stored in the DSI protocol engine is returned if the update is pending; otherwise, the values stored in the DSI PHY are returned.

10.3.4.4.6.2 DSI Busy Signal

The SCPBusy signal indicates there is still activity using the SCPClk clock provided by the PRCM module. The SCPClk clock is then divided by the DSS_L3_MAIN_ICLK/4 clock.

10.3.4.4.7 DSI Timers

NOTE: Among the timers described in this section, only the HS TX, LP RX, and TurnRequests timers generate interrupts immediately when the timer value is null. The ForceTxStopMode timer ends counting instantly and ForceTxStopMode is not asserted.

10.3.4.4.7.1 DSI T_{wakeup} Timer

The T_{WakeUp} timer is not implemented in the DSI protocol engine. The general-purpose (GP) timer must be used to handle wakeup. This timer is used for exiting ULPS for the active lanes (clock and/or data lanes). The sequence to exit ULPS is:

1. Change the state of TxULPSExit for each lane to ACTIVE.
2. Wait for the interrupt that indicates all lanes with TxULPSExit ACTIVE have acknowledged by asserting ULPSActiveNot. This is done by reading the ULPSACTIVENOT_ALLi_IRQ bit field (where i = 0 or 1) in the DSI_COMPLEXIO_IRQSTATUS register.
3. Start the application wake-up timer (GP timer).
4. Wait for the time-out.
5. Change the TxUlpsClk signals to INACTIVE state for the clock lane and/or TxRequestEsc INACTIVE state for the data lane(s).

NOTE: The minimum time for the wake-up period is 1 ms.

To enter ULPS for the clock lane, the state of TxUlpsClk must be changed to ACTIVE. To enter ULPS for the data lane, the state of TxRequestEsc must be changed to ACTIVE (also TxUlpsEsc, if it is not already in ACTIVE state).

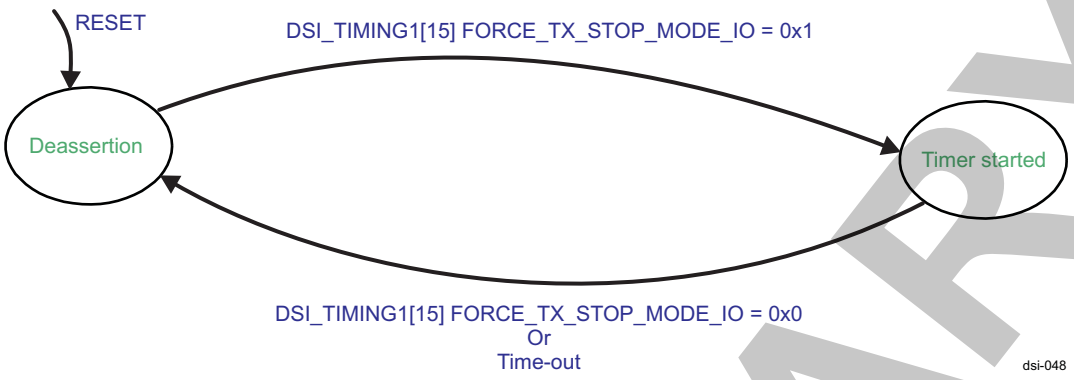
10.3.4.4.7.2 DSI ForceTxStopMode FSM

The ForceTxStopMode signal is used at initialization time (DSI PHY). Figure 10-134 shows the ForceTxStopMode finite state-machine (FSM) to assert and deassert the ForceTxStopMode signal.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-134. DSI ForceTxStopMode FSM



The DSI protocol engine asserts the ForceTxStopMode signal by setting the DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO bit to 1. Asserting the FORCE_TX_STOP_MODE_IO bit allows the lanes to be initialized. The lanes are in STOP state when the ForceTxStopMode signal is high.

No data can be sent before the ForceTxStopMode signal is deasserted. The deassertion time is defined by the STOP_STATE_COUNTER_IO, STOP_STATE_X4_IO, and STOP_STATE_X16_IO bit fields in DSI_TIMING1[14:0] register. The DSI_TIMING1[15:0] FORCE_TX_STOP_MODE_IO bit field is reset by hardware when the time is reached.

This bit can be reset by software.

The calculation of the number of DSI_CLK functional clock cycles assertion period is defined by:

Total period in DSI_FCLK cycles = STOP_STATE_COUNTER_IO × ((STOP_STATE_X16_IO x 15) + 1) × ((STOP_STATE_X4_IO × 3))

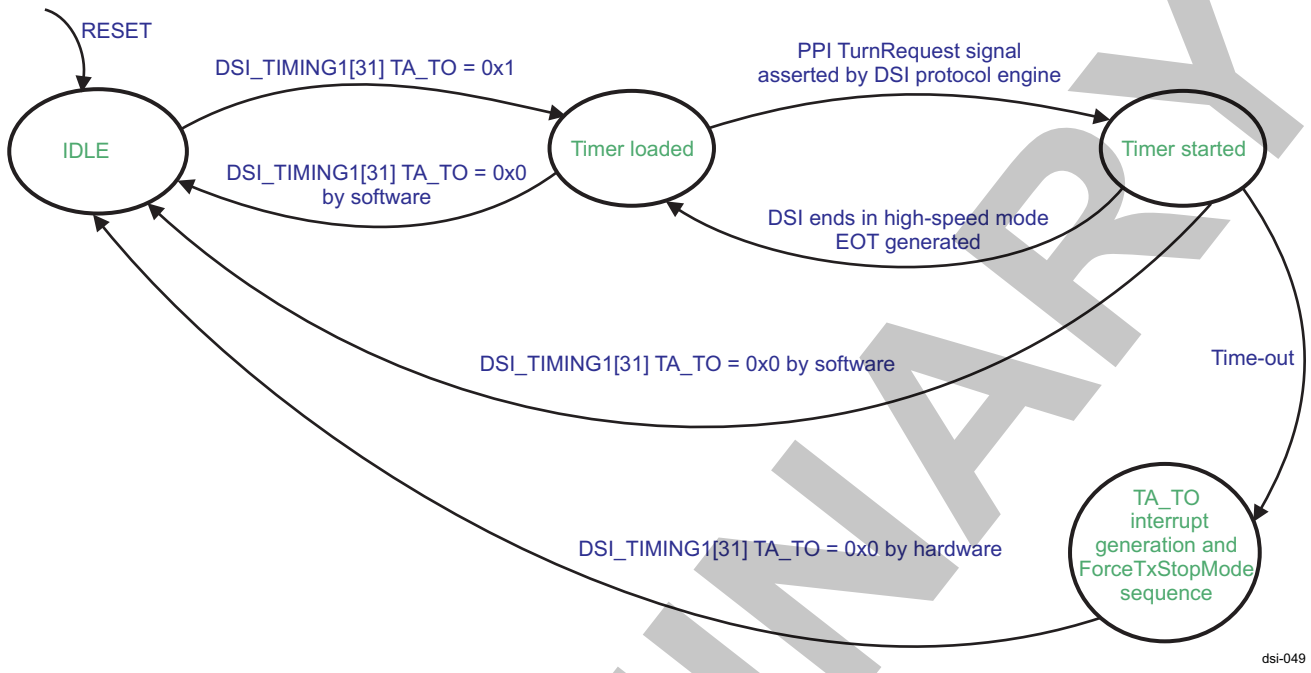
10.3.4.4.7.3 DSI TurnRequest FSM

The TurnRequest signal is used to request a turnaround. It is valid only for the first data lane, because the other data lanes cannot be used in reverse direction to receive data from the DSI receiver. When the TurnRequest signal is asserted, the TA_TO timer is started. Figure 10-135 shows the TurnRequest FSM to assert and deassert the TurnRequest signal.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-135. DSI TurnRequest FSM



The DSI protocol engine asserts the TurnRequest signal during one TxClkEsc cycle when turnaround is enabled through the DSI_VC_CTRL_i[6] BTA_EN bit (for more information, see Section 10.3.4.4.8, *Bus Turnaround*). The DSI_TIMING1[31] TA_TO bit is set/reset by software to enable or disable the timer for turnaround procedure failure. It can be reset by software or automatically by hardware when the time-out occurs.

The timer is loaded with the value in the number of DSI_FCLK cycles:

DSI_TIMING1[28:16] TA_TO_COUNTER × ((DSI_TIMING1[30] TA_TO_X16 × 15) + 1) × ((DSI_TIMING1[29] TA_TO_X8 × 7) + 1)

When the TA_TO_IRQ interrupt is generated (the turnaround timer expired and the procedure failed), hardware automatically resets the DSI_TIMING1[31] TA_TO bit and asserts the ForceTXStopMode signal (see Section 10.3.4.4.7.2, *ForceTxStopMode FSM*) for the DSI_PHY_DSS_x to drive the LP-11 STOP state. The ForceTXStopMode timer is used to define the minimum duration of the LP-11 state. The STOP state can be longer if there is no activity.

Hardware resets the DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO bit, followed by an internal logic reset except for all register values and TX FIFO content, and then resets the DSI_CTRL[0] IF_EN bit. Software must take action to recover (for example, by resetting the peripheral if it is not responding). It must wait for the DSI_CTRL[0] IF_EN bit to be reset to 0 before starting the recovery sequence.

10.3.4.4.7.4 DSI Peripheral Reset Timer

The peripheral reset timer is not implemented in the DSI protocol engine module. Instead, a GP timer must be used in case of reset of the peripheral to determine when the peripheral is ready to operate again.

10.3.4.4.7.5 DSI HS TX Timer

The HS TX timer is used to detect when the host is in TX mode too long. When time-out occurs, the EOT is forced. The timer is reloaded when a start of HS transmission occurs. It is enabled and disabled by software through the DSI_TIMING2[31] HS_TX_TO bit. The HS_TX_TO_IRQ interrupt is generated when the timer expires. The DSI_IRQSTATUS[14] HS_TX_TO_IRQ bit is set to 1 when the HS TX time-out occurs.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

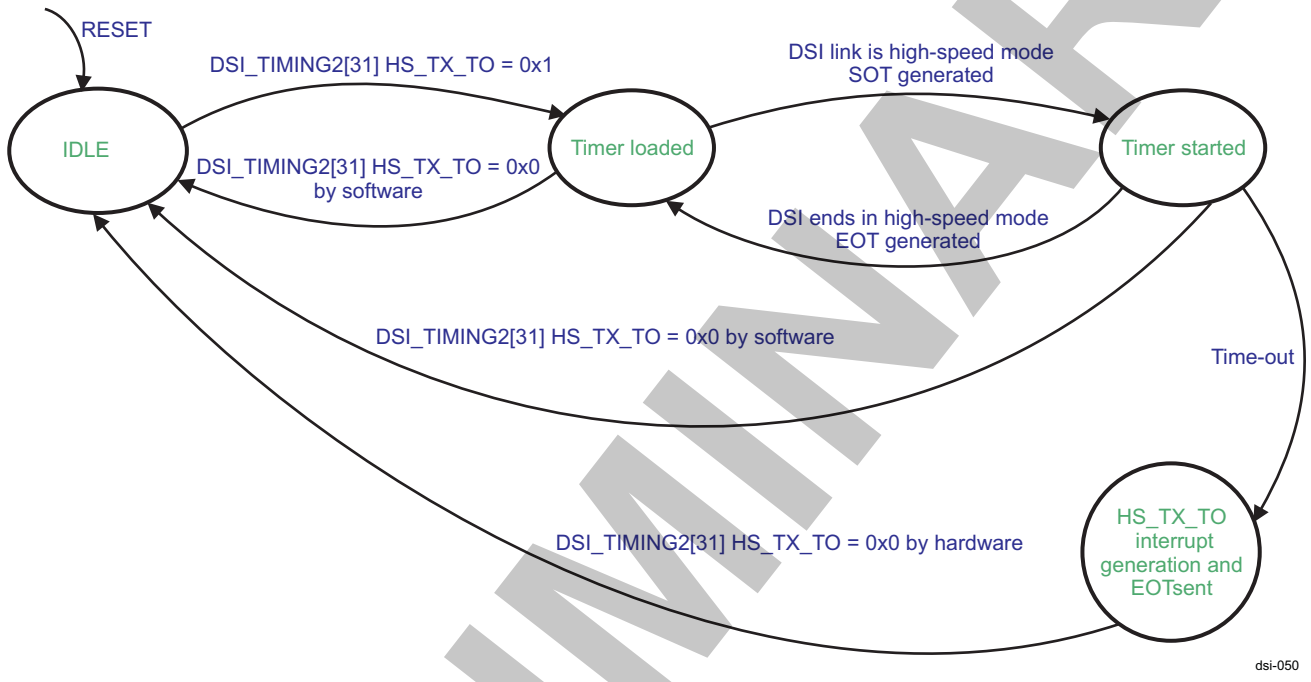
The maximum time supported is 20 ms. It can be used to determine that at least once per frame in video mode, the HS mode is stopped to enter ULPS.

The timer is loaded with the value in the number of TXBYTECLKHS:

DSI_TIMING2[28:16] HS_TX_TO_COUNTER × (1 + (DSI_TIMING2[30] HS_TX_TO_X64 × 63)) × (1 + (DSI_TIMING2[29] HS_TX_TO_X16 × 15))

Figure 10-136 shows the HS TX timer FSM.

Figure 10-136. DSI HS TX Timer FSM



When the time-out occurs, hardware sends an EOT request for the DSI PHY to drive LP-11 STOP state. This is followed by the generation of the interrupt. Hardware performs an internal logic reset including the TX FIFO content but excluding the register values, and then resets the DSI_CTRL[0] IF_EN bit.

Software must take action to recover (for example, by resetting the peripheral if it is not responding). It must wait for the DSI_CTRL[0] IF_EN bit to be reset to 0 before taking any recovery action.

10.3.4.4.7.6 DSI LP RX Timer

When the host is in low-power receive mode after a BTA, the LP RX timer is loaded. When the timer expires, the host requests the DSI PHY to drive LP-11. The LP_RX_TO_IRQ interrupt is generated when the timer expires. The DSI_IRQSTATUS[15] LP_RX_TO_IRQ bit is set to 1 when the LP RX time-out occurs.

The DSI_TIMING2[15] LP_RX_TO bit is set and reset by software to enable or disable the timer.

The timer is loaded with the value in the number of DSI_CLK functional clock cycles:

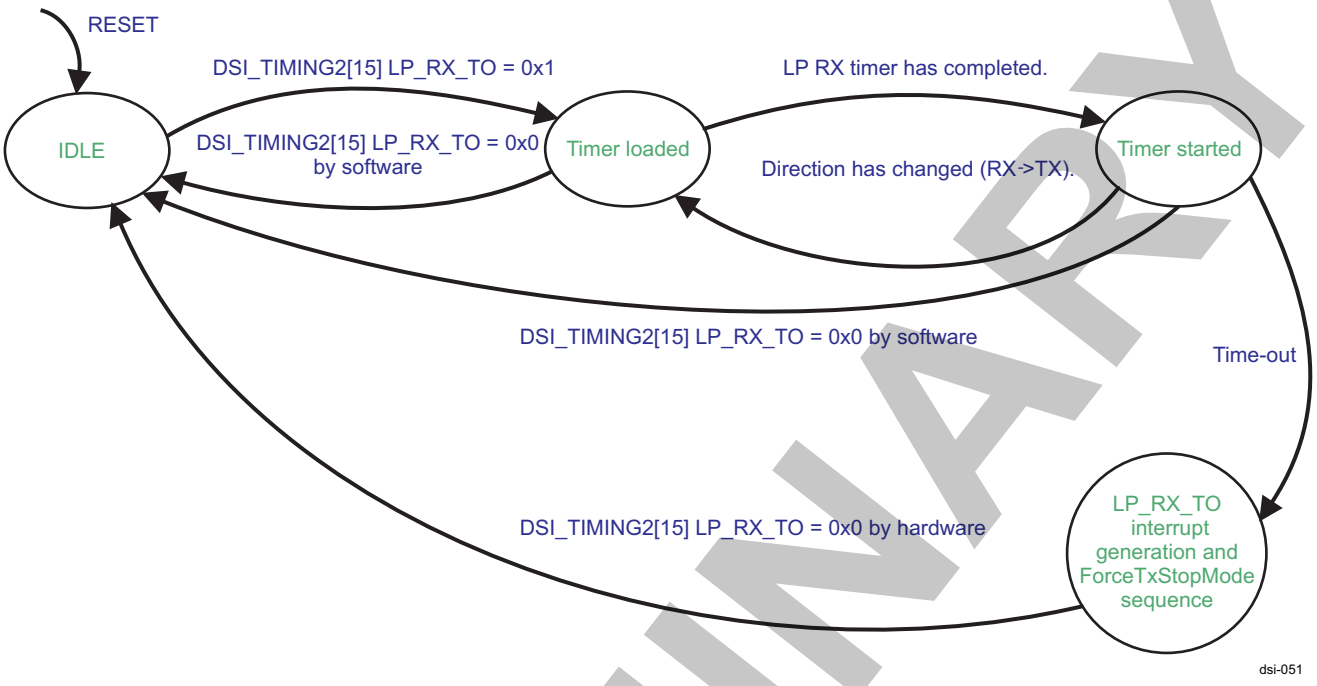
DSI_TIMING2[12:0] LP_RX_TO_COUNTER × ((DSI_TIMING2[14] LP_RX_TO_X16 × 15) + 1) × ((DSI_TIMING2[13] LP_RX_TO_X4 × 3) + 1)

Figure 10-137 shows the LP RX timer FSM.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-137. DSI LP RX Timer FSM



When the interrupt is generated, hardware automatically resets the DSI_TIMING2[15] LP_RX_TO bit and then asserts ForceTXStopMode for the DSI PHY to drive LP-11 STOP state. The ForceTXStopMode timer is used to define the minimum duration of the LP-11 state. The STOP state can be longer if there is no activity.

Hardware resets the FORCE_TX_STOP_MODE bit, followed by an internal logic reset except for all register values and TX FIFO content, and then resets the DSI_CTRL[0] IF_EN bit. Software must take action to recover (for example, by resetting the peripheral if it is not responding). It must wait for the DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO and DSI_CTRL[0] IF_EN bits to be reset before starting the recovery sequence. The TX FIFO is not flushed (the FIFO is flushed only when the DSI_VC_CTRL_i[0] VC_EN is set to 1).

10.3.4.4.8 DSI Bus Turnaround

The BTA is not automatically sent by default after each packet is sent to the panel(s). It is programmable independently for each VC ID. BTA generation can be enabled when the DSI_VC_CTRL_i[6] BTA_EN bit is set to 1 by software. Software must ensure that when the BTA is sent to the peripheral, enough time is allocated for the response and for the BTA from the peripheral to the host. For more information about possible DSI PHY timing adjustments during the turnaround procedure, see Section 10.3.4.6.5.3, *Turnaround Request in Transmit Mode*, and Section 10.3.4.6.5.4, *Turnaround Request in Receive Mode*.

When setting the DSI_VC_CTRL_i[6] BTA_EN bit to 1, one BTA is sent manually to the peripheral. This manual mode can be used for packets in command or video mode.

Acknowledgment from the peripheral for successful BTA is indicated by asserting the BTA_IRQ interrupt, if it is enabled in the DSI_VC_IRQENABLE_i[5] BTA_IRQ_EN bit. To monitor the BTA interrupt, the user must read the DSI_VC_IRQSTATUS_i[5] BTA_IRQ status bit.

CAUTION

The BTA should be sent when the RX FIFO is empty. Users must empty the RX FIFO before sending the BTA to the peripheral to ensure that when receiving new data from the peripheral, the allocated spaces for all the VCs are empty.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

In automatic mode, the BTA is sent automatically at the end of short or long packet transmission, if the DSI_VC_CTRL_i[2] BTA_SHORT_EN or DSI_VC_CTRL_i[3] BTA_LONG_EN bit is set to 1.

Two modes can be used for each VC ID:

- Automatic: After each packet, a BTA is sent. To determine the size of the long packet, the protocol engine on the host side reads the word count defined in the header (in the DSI_VC_LONG_PACKET_HEADER_i register) and uses it to determine the last data to be sent on the DSI link. For short packets, the size is always 4 bytes. The BTA is then sent to the peripheral. The word count is also used to determine how many bytes are to be transferred from the 32-bit write access to the payload register (DSI_VC_LONG_PACKET_PAYLOAD_i).
- Manual:
  - Data transfer through L3_MAIN interconnect: When transferring data using the L3_MAIN interconnect port, while all data have been provided to the DSI protocol engine, users can select the BTA for the last packet provided to the L3_MAIN interconnect port only by setting the DSI_VC_CTRL_i[6] BTA_EN bit, or for the last packets and the following ones by setting automatic mode.
  - Data transfer through video port: In the case of data transfer using the video port, the DSI_VC_CTRL_i[6] BTA_EN bit can be selected at any time during the transfer of the packet.
- For video mode packets (data and synchronization events), it is not possible to determine when the BTA is sent; therefore, it is highly recommended to use manual BTA mode only in command mode. It is possible, however, to use the BTA for a VC in video mode.

  For data provided on the video port, an interrupt for end of packet transfer PACKET_SENT_IRQ is provided to indicate when the packet is completely sent by the DSI PHY. PACKET_SENT_IRQ can be monitored in the DSI_VC_IRQSTATUS_i[2] PACKET_SENT_IRQ status bit. The BTA is available even if the space allocated in the TX FIFO for the corresponding VC is empty. It must be sent later even if no packet was sent before the BTA request. The DSI_VC_CTRL_i[6] BTA_EN bit must be reset if the BTA request was sent, even if automatic mode for this specific type of packets is enabled.

The BTA is supported for video and command mode packets. It is not possible to send the BTA during the blanking periods of video mode when HS blanking packets should be sent; that is, when one of the following bits is set to 1:

- DSI_CTRL[20] BLANKING_MODE
- DSI_CTRL[21] HFP_BLANKING_MODE
- DSI_CTRL[22] HBP_BLANKING_MODE
- DSI_CTRL[23] HSA_BLANKING_MODE

Therefore, in video mode, the BTA request is delayed until there is a blanking period without HS blanking packets.

When the TurnRequest signal is asserted (always only for the first data lane), the TA_TO timer is started. If the direction signal is not changed according to the turnaround request, the TA_TO interrupt is generated. When the direction signal is in output mode, any data on the input data bus is ignored because the DSI is in transmission mode (data and triggers must be ignored). For more information about the TA_TO timer, see Section 10.3.4.4.7.3, *TurnRequest FSM*.

10.3.4.4.9 DSI PHY Triggers

The DSI protocol engine uses three triggers that are supported only for the first data lane:

- Reset trigger from host to display
- TE trigger from display to host
- Acknowledge trigger from display to host

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

CAUTION

Each trigger is associated with a dedicated user-configurable receive or transmit pattern, which is loaded in the DSI_PHY_REGISTER3 or DSI_PHY_REGISTER4 register. The default (reset) values of the bit fields are aligned with the *MIPI D-PHY Specification v1.01.00 Revision 0.02*. If any of these values need to be changed, the following must be considered:

- If any of the bit fields is written with a nondefault value, the other bit fields in the same register must also be configured with different values. This ensures that two different trigger bit fields are not programmed with the same pattern.
- If two or more bit fields are written with equal values, unpredictable behavior of the DSI PHY module may occur.

10.3.4.4.9.1 DSI Reset

The DSI protocol engine can use one of the triggers of the DSI_PHY_DSS_x to send a reset to the display. The reset trigger pattern is configurable through the DSI_PHY_REGISTER3[31:24] REG_TXTRIGGERESC3 bit field. To send the reset pattern to the peripheral, the DSI_CTRL[5] TRIGGER_RESET bit must be set to 1. When software requires the trigger reset pattern to be sent, the DSI protocol engine resets its own logic, but not the registers. Software can select between two reset modes:

- Immediate reset: All pending requests in TX FIFO not already considered for transfer scheduling, the RX FIFO requests, and the data from video port are ignored. Only the current transfer on the DSI link and those already scheduled are transmitted. All the other transfers are discarded.
- Synchronized reset: The mode is valid only if a VC is using the video mode and it is active. The principle is to wait for the current video frame to be transferred on the link. Any data on the video port after the current frame are ignored.

To select reset mode, the DSI_CTRL[14] TRIGGER_RESET_MODE bit must be programmed.

NOTE: For both reset modes, the DSI protocol engine flushes the FIFOs, synchronization buffers, and line buffers before resetting the DSI_CTRL[0] IF_EN bit.

10.3.4.4.9.2 DSI Tearing Effect

TE on the display is avoided by having synchronization information from the display. It is used only in command mode and is not functional in video mode.

The two types of TE triggers are:

- DSI PHY TE trigger
- CMOS TE line (one of the two input signals can be selected for the TE trigger of a VC; the signal is asynchronous)

Software must set and send the appropriate sequence to receive the TE trigger pattern from the peripheral on the DSI link, or use the CMOS TE line. The value of the expected TE trigger pattern can be configured through the DSI_PHY_REGISTER4[23:16] REG_RXTRIGGERESC2 bit field.

When the TE PHY trigger pattern is received, the DSI protocol engine generates the TE_TRIGGER_IRQ interrupt with a TE event if the interrupt is enabled. To enable the interrupt, the DSI_IRQENABLE[16] TE_TRIGGER_IRQ_EN bit must be set to 1. The DSI_IRQSTATUS[16] TE_TRIGGER_IRQ status bit indicates whether the interrupt event has been generated.

When using the TE CMOS signal, the DSI protocol engine generates the TE0_LINE or TE1_LINE interrupt, if it is enabled, depending on which line is used. One or multiple VCs can be synchronized using the same TE line. Both lines can be active at the same time for different VCs.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The DSI_VC_TE_i[30] TE_EN bit must be set and the DSI_VC_TE_i[29] TE_LINE bit must be reset to indicate that hardware must use the TE PHY trigger to start the transfer of the data from the related VC. TE_EN is reset when all the data are sent to the peripheral.

The DSI_VC_TE_i[30] TE_EN, DSI_VC_TE_i[29] TE_LINE, and DSI_VC_TE_i[28] TE_LINE_NB bits must be set to select between the TE0 and TE1 line to indicate that hardware must use the TE0 or TE1 line to start the transfer of the data from the related VC. The bits are reset when all the data are sent to the peripheral.

The DSI_TE_VSYNC_WIDTH_j, DSI_TE_HSYNC_WIDTH_j, and DSI_TE_HSYNC_NUMBER_j registers indicate which mode is used to detect the start of the transfer:

- If DSI_TE_HSYNC_NUMBER_j[10:0] LINE_NUMBER = 0, DSI_TE_HSYNC_WIDTH_j is ignored. When a pulse on the TE line is detected to be wider than the DSI_TE_VSYNC_WIDTH_j[19:8] MIN_VSYNC_PULSE_WIDTH bit field, data transfer starts from the protocol engine to the peripheral at the falling edge of the TE CMOS line.
- If the DSI_TE_HSYNC_NUMBER_j[10:0] LINE_NUMBER bit field is greater than 0, DSI_TE_HSYNC_WIDTH_j is used. The DSI protocol engine waits until it detects a pulse wider than the DSI_TE_VSYNC_WIDTH_j[19:8] MIN_VSYNC_PULSE_WIDTH bit field, and then counts each pulse wider than DSI_TE_HSYNC_WIDTH_j[19:8] MIN_HSYNC_PULSE_WIDTH, but smaller than DSI_TE_VSYNC_WIDTH_j[19:8] MIN_VSYNC_PULSE_WIDTH. When the number of HSYNC pulses is reached, data transfer from the DSI protocol engine to the peripheral starts. In case the number of HSYNC pulses is not reached due to a new VSYNC pulse being detected, the counter of HSYNC pulses restarts from 0.

NOTE: The DSI_TE_HSYNC_WIDTH_j[19:8] MIN_HSYNC_PULSE_WIDTH is always programmed with a value smaller than the DSI_TE_VSYNC_WIDTH_j[19:8] MIN_VSYNC_PULSE_WIDTH bit field.

NOTE: The following must always be set before the DSI_VC_TE_i[30] TE_EN bit is enabled:

- DSI_TE_HSYNC_WIDTH_j[19:8] MIN_HSYNC_PULSE_WIDTH
- DSI_TE_VSYNC_WIDTH_j[19:8] MIN_VSYNC_PULSE_WIDTH
- DSI_VC_TE_i[29] TE_LINE
- DSI_VC_TE_i[28] TE_LINE_NB

The DSI_VC_TE_i[31] TE_START bit must be used when automatic mode is disabled (the DSI_VC_TE_i[30] TE_EN bit is set to 0). It lets users start the transfer manually based on application events or based on the TE trigger interrupt (TE_TRIGGER_IRQ).

The number of bytes to be transferred is defined by using the DSI_VC_TE_i[23:0] TE_SIZE bit field. The TE_SIZE bit field is decremented for each payload byte (it does not include checksum) sent on the DSI link. The register content must not be modified by software during a transfer. The DSI_VC_TE_i[23:0] TE_SIZE bit field must be set first to indicate that the following accesses to the DSI_VC_LONG_PACKET_HEADER_i register must be used for TE transfer.

The data can be provided from two sources (select by setting the DSI_VC_CTRL_i[1] SOURCE bit):

- L3_MAIN interconnect slave port using DMA request: The DMA request DSI_DMA_REQi must be asserted only when the TE trigger is received or when the DSI_VC_TE_i[31] TE_START bit is set by the user and must no longer be asserted when all the bytes defined in the DSI_VC_TE_i[23:0] TE_SIZE bit field are sent on the DSI link. The VC is associated with a DMA request by programming the number in the DSI_VC_CTRL_i[23:21] DMA_TX_REQ_NB bit field. The DSI_VC_LONG_PACKET_PAYLOAD_i register is used to provide the number of bytes defined by the DSI_VC_TE_i[23:0] TE_SIZE bit field (the checksum value is not provided in the DSI_VC_LONG_PACKET_PAYLOAD_i register). The size of the header is not considered in the number of bytes to transfer. The DSI_VC_SHORT_PACKET_HEADER_i register is not used.

NOTE: All DMA requests associated to a VC must be disabled when they are not used (DSI_VC_CTRLi[23:21] DMA_TX_REQ_NB = 0x4).

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- Video port: The DMA request is not asserted. The data are captured in the line buffer using the STALL mechanism. If no line buffer is instantiated (that is, the DSI_CTRL[13:12] LINE_BUFFER bit field is set to 0), it is not possible to use the video port to provide data. The line buffer is filled according to the word count defined in the DSI_VC_LONG_PACKET_HEADER_i register header. The value must be written before the TE trigger event is received or before the DSI_VC_TE_i[31] TE_START bit is set to 1 by software. If the total number of bytes defined by the DSI_VC_TE_i[23:0] TE_SIZE bit field is not a multiple of the word count defined in the DSI_VC_LONG_PACKET_HEADER_i register, all the packets are the same size defined by the WC of the header, except the last transfer. The size of the last transfer is defined by the remaining bytes to send. Because the DSI_VC_TE_i[23:0] TE_SIZE bit field is modified after each packet transfer, the size of the last packet is equal to the value of the DSI_VC_TE_i[23:0] TE_SIZE bit field before the last transfer (the header and the payload checksum sizes are not included in the DSI_VC_TE_i[23:0] TE_SIZE bit field).

When the transfer completes, the value of the DSI_VC_TE_i[23:0] TE_SIZE bit field is equal to 0. Software must ensure that the pending data in the TX FIFO for the corresponding VC using TE are related to the TE transfer. Any data in the TX FIFO that must be sent before the reception of the TE trigger must be sent before the TE. This is done by not enabling the TE trigger until all data for the corresponding VC are sent to the peripheral. Software can check that the space allocated for the VC in the TX FIFO is empty by reading the DSI_VC_CTRL_i[5] TX_FIFO_NOT_EMPTY status bit.

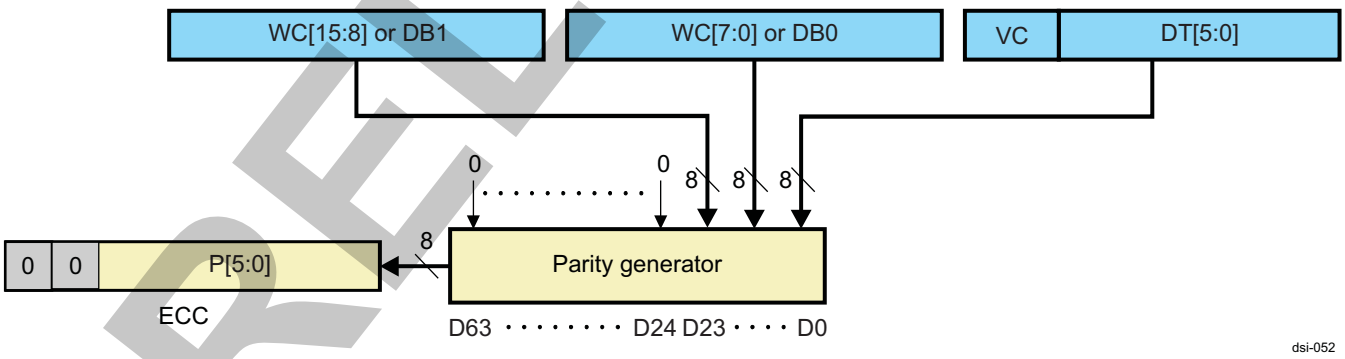
10.3.4.4.9.3 DSI Acknowledge

The corresponding acknowledge interrupt (ACK_TRIGGER_IRQ) is generated when the acknowledge trigger is received. The value of the expected acknowledge trigger pattern can be configured through the DSI_PHY_REGISTER4[15:8] REG_RXTRIGGERESC1 bit field. To enable the acknowledge interrupt, set the DSI_IRQENABLE[17] ACK_TRIGGER_IRQ_EN bit to 1. When the interrupt is generated, the DSI_IRQSTATUS[17] ACK_TRIGGER_IRQ status bit is set to 1.

10.3.4.4.10 DSI ECC Generation

The DSI protocol uses a 4-byte PH. Because ECC generation requires a fixed word length of 64-bits, the packet headers must be padded with additional bits to form a full 8-byte value for ECC generation and checking. The PH minus the ECC byte should occupy bits D[23:0], and the pad bits should occupy bits D[63:24]. All padding bits must be 0 to generate the ECC byte. ECC can be generated using a parallel approach, as shown in Figure 10-138.

Figure 10-138. DSI 64-Bit ECC Generation on TX Side



The ECC generation/check can be enabled and disabled by software. It is defined by a common bit for all the VCs:

- The DSI_CTRL[2] ECC_RX_EN bit enables and disables ECC generation in the receive direction.
- The DSI_VC_CTRL_i[8] ECC_TX_EN bit enables and disables ECC generation in the transmit direction

The ECC can be provided while writing the ECC value directly into the DSI_VC_LONG_PACKET_HEADER_i and DSI_VC_SHORT_PACKET_HEADER_i registers. The DSI_VC_CTRL_i[8] ECC_TX_EN bit indicates whether the ECC value will be calculated or whether the value written in the register will be used instead for command and video modes.

PRELIMINARY

10.3.4.4.11 DSI Checksum Generation for Long Packet Payloads

Long packets consist of a PH protected by an ECC byte and a payload of 0 to $2^{16} - 1$ bytes. To detect the errors during the transmission of long packets, a checksum is calculated over the payload portion of the data packet. For the special case of a 0-length payload, the 2-byte checksum is set to 0xFFFF. The checksum can indicate only the presence of one or more errors in the payload. Unlike ECC, the checksum does not enable error correction. For this reason, checksum calculation is not useful for some unidirectional DSI implementations, because the peripheral has no way to report errors to the host processor. Checksum generation and transmission is mandatory for host processors sending long packets to peripherals; it is optional for peripherals transmitting long packets to the host processor. However, the format of long packets is fixed; the peripherals that do not support checksum generation must transmit 2 bytes with a value of 0x0000 in place of the checksum bytes when sending long packets to the host processor. The host processor must disable checksum checking for received long packets from peripherals that do not support checksum generation.

Checksum must be realized as a 16-bit CRC with a generator polynomial of $x^{16} + x^{12} + x^5 + x^0$. The LSByte is sent first, followed by the MSByte. Within the byte, the LSB is sent first.

Figure 10-139 shows the checksum transmission.

Figure 10-139. DSI Checksum Transmission

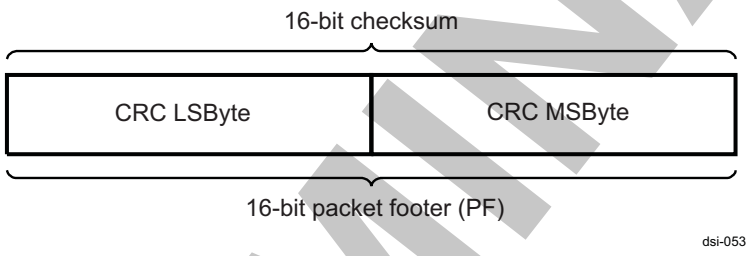

Figure 10-140 shows the CRC implementation. The CRC shift register is initialized to 0xFFFF before packet data enters. Packet data not including the PH then enters as a bitwise data stream from the left, LSB first. Each bit is fed through the CRC shift register before it is passed to the output for transmission to the peripheral. After all bytes in the packet payload have passed through the CRC shift register, the shift register contains the checksum. C15 contains the MSB of the checksum, and C0 contains the LSB of the 16-bit checksum. The checksum is then appended to the data stream and sent to the receiver.

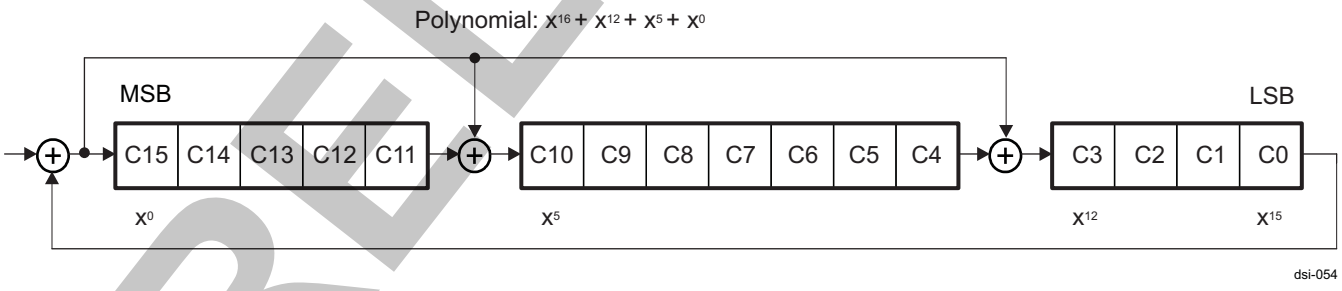
Figure 10-140. DSI 16-Bit CRC Generation Using a Shift Register



Checksum generation/check can be enabled and disabled by software. It is defined by a common bit for all the VCs:

- The DSI_CTRL[1] CS_RX_EN bit enables and disables checksum generation in the receive direction.
- The DSI_VC_CTRL_i[7] CS_TX_EN bit enables and disables checksum generation in the transmit direction.

10.3.4.4.12 DSI EOT Packet

A new packet type allows the DSI protocol (rather than the DSI_PHY_DSS_x) at the display to detect the HS EOT. This is a fixed short packet (4 bytes) that is added at every HS-to-LP transition. This function is enabled by the DSI_CTRL[19] EOT_ENABLE bit.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The EOT packet has a fixed format:

- Data Type = DI [5:0] = 0b001000
- Virtual Channel = DI [7:6] = 0b00
- Payload Data [15:0] = 0x0F0F
- ECC [7:0] = 0x01

When more that one data lane is used, the EOT packet bytes are distributed across the multiple lanes. EOT packet generation is supported only for the end of HS transmissions. No EOT packet is added at the end of LP transmissions. For LP reception, any EOT packet received is simply passed through as any other packet, but no internal decode or use is made of the EOT information.

10.3.4.4.13 DSI Software Reset

The DSI protocol engine can be reset by software. This reset can be done for debug purposes or after a protocol error and has the same effect as the hardware reset. The DSI protocol engine can be reset by setting the DSI_SYSCONFIG[1] SOFT_RESET bit to 1. Software can monitor the DSI_SYSSTATUS[0] RESET_DONE status bit to wait for the reset to complete. If after five reads the DSI_SYSSTATUS[0] RESET_DONE status bit still returns 0, it can be assumed that an error occurred during the reset stage.

NOTE: This software reset is optional because a hardware reset is always performed on the DSI protocol engine at device reset.

10.3.4.4.14 DSI Power Management

The power-management behavior of the DSI protocol engine is controlled by the DSI_SYSCONFIG register. This register controls the way the module interacts with the PRCM module. The DSI_SYSCONFIG[0] AUTO_IDLE bit must be set to 1 (default value) to enable automatic clock gating in the module.

The DSI protocol engine implements a handshake protocol on the L3_MAIN interconnect slave port with the PRCM module. The protocol engine provides control signal CIO_CLK_ICG to gate the SCPClk (DSS_L3_MAIN_ICLK/4). It allows the reduction of power consumption of the DSI PHY when the DSI link is not in use (the DSI_CLK_CTRL[14] CIO_CLK_ICG bit).

10.3.4.4.15 DSI Power Control of DSI PHY and DSI PLL

The DSI protocol engine can control and send power commands for the DSI PHY and DSI PLL controller modules.

10.3.4.4.15.1 DSI PHY Control Commands

10.3.4.4.15.1.1 DSI PHY Control Commands

The DSI PHY can be set in three modes:

- OFF: In this power state, the complete DSI_PHY_DSS_x circuit is powered down. The internal LDO is OFF.
- ON: In this power state, the complete DSI_PHY_DSS_x circuit is powered on and functional.
- ULPS: In this power state, the ULPS exit detection circuit power switch is ON for the lanes that are in receive ULPS. For the lanes that are in transmit ULPS, the circuitry for weak pulldown is ON. ULPS must be used only when all three lanes are in ULPS (transmit or receive).

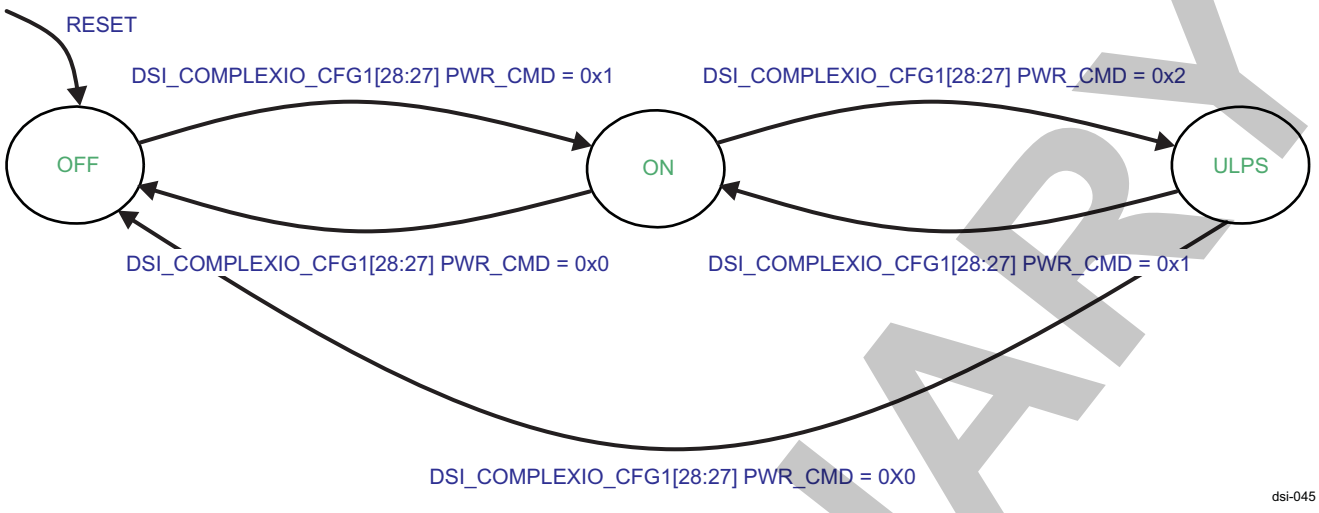
10.3.4.4.15.1.2 DSI PHY Power FSM

Figure 10-141 shows the FSM to control the power state of the DSI PHY

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-141. DSI PHY Power FSM



The following commands control the state transition of the DSI PHY:

- PwrCmdOff
- PwrCmdUlp
- PwrCmdOn

The DSI_COMPLEXIO_CFG1[28:27] PWR_CMD bit field allows the state to be modified. The allowed transitions are: OFF–ON, ON–ULPS, and ULPS–OFF. The DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS bit field gives a status on the current state of the DSI PHY.

CAUTION

- In automatic mode, software must ensure that the DSI PHY is in ON state (that is, ON command already sent) before sending requests to the DSI PHY.
- In a command request to change to a state that is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI PHY).
- To change the state to ULPS, all ULPSActiveNot signals must be low. The ULPSActiveNot_ALL0_IRQ interrupt indicates the state of the ULPSActiveNot signals. The change from ULPS to ON state is required before starting the ULP exit sequence (for more information, see Section 10.3.4.4.7.1, *T_{wakeup} Timer*).

10.3.4.4.15.2 DSI PLL Power Control Commands

The DSI PLL controller module can be set in four modes:

- OFF: DSI PLL and HSDIVIDER are OFF.
- ON ALL: DSI PLL and HSDIVIDER are ON. The CLKIN2DDR clock is provided to the DSI PHY, and the second clock output is provided to the HSDIVIDER.
- ON HSCLK: The DSI PLL is ON. The HSDIVIDER is OFF. The CLKIN2DDR clock is provided to the DSI PHY, but the second clock output is not provided to the HSDIVIDER.
- ON DIV: DSI PLL and HSDIVIDER are ON. The CLKIN2DDR clock is not provided to the DSI PHY, but the second clock output is provided to the HSDIVIDER.

10.3.4.4.15.2.1 DSI PLL Power FSM

Figure 10-142 shows the power state of the DSI PLL.

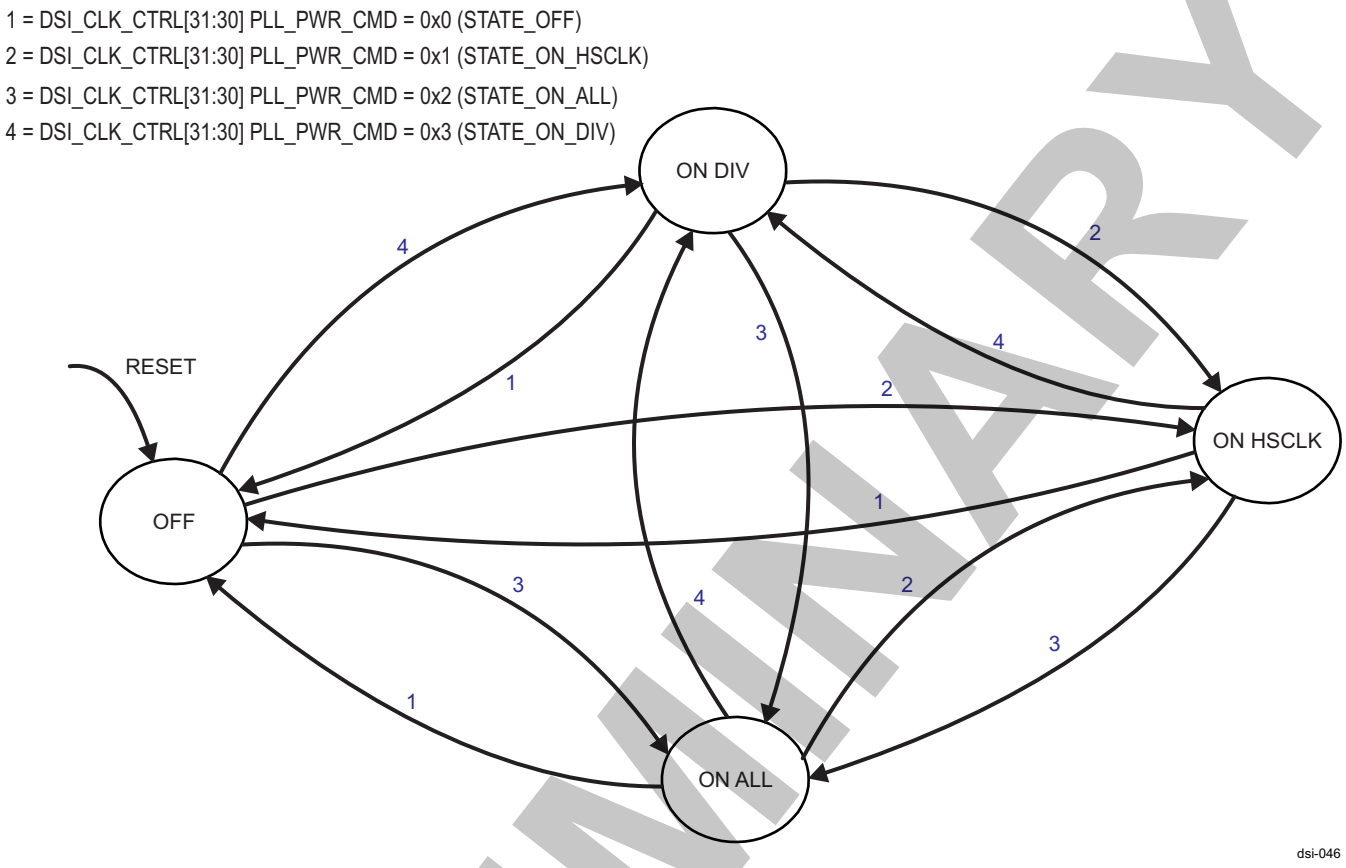
PRELIMINARY

Figure 10-142. DSI PLL Power FSM



The following commands control the state transition of the DSI PLL control module:

- PLLPwrCmdOff
- PLLPwrCmdOnAll
- PLLPwrCmdOnDIV
- PLLPwrCmdOnHSClk

Setting the DSI_CLK_CTRL[31:30] PLL_PWR_CMD bit field modifies the state. The DSI_CLK_CTRL[29:28] PLL_PWR_STATUS bit field gives a status on the current state of the DSI PLL controller.

NOTE: If a command requests to change to a state that is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI PLL control module).

10.3.4.4.15.2.1.1 DSI PLL HS Clock Signals

The DSIStopClk signal is provided to the DSI PLL control module. It indicates when the DSI protocol engine does not need to use HS mode and the PLL HS output (CLKIN2DDR clock) can be stopped. The following conditions must also be met when DISPC_UPDATE_SYNC may be generated by the DISPC, because that must result in the PLL HS output being stopped.

When the interface is disabled (the DSI_CTRL[0] IF_EN bit set to 0) and the clock lane is stopped (DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON = 0), the DSIStopClk signal is asserted.

Assertion of DSIStopClk depends on the following conditions:

- Clock lane TxRequestHS is deasserted (the DDR clock on the clock lane is no longer required). For deassertion of TxRequestHS, the following conditions are required:

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- The DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit must be reset to 0 and no HS data transfer must be ongoing or already scheduled.
- No VC ACTIVE in video mode. No VC using the video mode is enabled. If the VC is enabled, the mode is command mode only (the DSI_VC_CTRL_i[0] VC_EN bit set to 1 and the DSI_VC_CTRL_i[4] MODE bit set to 0).
- No command mode requiring HS transfer (one or more VCs using command mode can be active)
- Or the DSI_CTRL[0] IF_EN bit is reset to 0 (the previous conditions are not all required, except the DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit must be set to 0 after resetting the DSI_CTRL[0] IF_EN bit)

Deassertion of DSIStopClk depends on one of the following conditions (the DSI interface is enabled by setting the DSI_CTRL[0] IF_EN bit to 1):

- Clock lane TxRequestHS must be asserted (the DDR clock on the clock lane is required).
- One video mode VC ACTIVE
- At least one VC in command mode requiring HS transfer
- The DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit is set to 1 by software users (the DSI_CTRL[0] IF_EN bit must be reset to 0 for updating the value of the DDR_CLK_ALWAYS_ON bit).

Automatic assertion/deassertion is enabled by using the DSI_CLK_CTRL[18] HS_AUTO_STOP_ENABLE bit.

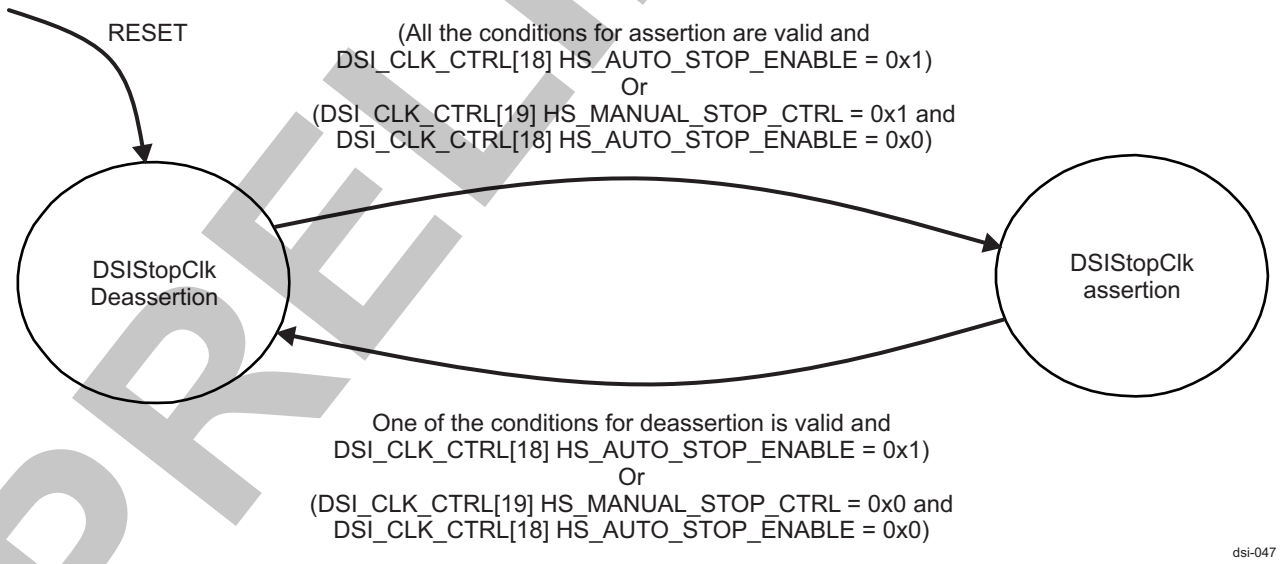
Manual mode can be used by setting and resetting the DSI_CLK_CTRL[19] HS_MANUAL_STOP_CTRL bit to assert or deassert the DSIStopClk signal.

NOTE: Setting the DSI_CTRL[24] DISPC_UPDATE _SYNC bit to 0x1 enables the use of the Dispc_Update_Sync signal to synchronize.

10.3.4.4.15.2.1.2 DSI PLL HS Clock FSM

Figure 10-143 shows the DSI PLL HS clock FSM.

Figure 10-143. DSI PLL HS Clock FSM



When DSIStopClk is used, there is a latency through other modules (DSI PLL controller and DSI_PHY_DSS_x) before TXBYTECLKHS is stopped. This latency must be considered to prevent any issue when DSIStopClk is deasserted soon after being asserted. This is done using a hardware timer programmed using the DSI_STOPCLK_TIMING[7:0] DSI_STOPCLK_LATENCY bit field. This timer is programmed in a number of periods of the DSI protocol functional clock (DSI_CLK). At the reset value, the timer is programmed with the value 0x80 (128).

Copyright © 2013, Texas Instruments Incorporated
PRELIMINARY

CAUTION

The programmed value in the DSI_STOPCLK_TIMING[7:0] DSI_STOPCLK_LATENCY bit field must be greater than ((3 × L3_MAIN_ICLK period) + (5 × CLKIN2DDR period)) / (DSI_CLK period).

10.3.4.4.16 DSI ULPS Configuration

This section describes how to enter and exit ULPS.

NOTE: The DSI_COMPLEXIO_CFG2[9:0] LANEx_ULPS_SIGy bit field (***where x*** = 1 to 5, corresponding to the five lanes of DSI1_A, and DSI1_C; ***and where y*** = 1 to 2) must be read back after writing to verify that the write operations are effective before proceeding to the next step. This considers low TxClkEsc frequencies.

10.3.4.4.16.1 DSI Entering ULPS

To enter ULPS for a clock lane, the following sequence is required:

1. Wait for the DSI_COMPLEXIO_CFG2[16] HS_BUSY and DSI_COMPLEXIO_CFG2[17] LP_BUSY bits to be reset to 0 and ensure that the DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit is 0.
2. The state of TxUlpsClk changes from INACTIVE to ACTIVE by setting the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 bit field to 1.

To enter into ULPS for a data lane, the following sequence is required:

1. Wait until all TX_FIFOs for all VCs working in HS are empty, video mode is not active, and the DSI_COMPLEXIO_CFG2[16] HS_BUSY bit is reset to 0 (in addition for the first data lane, the DSI_COMPLEXIO_CFG2[17] LP_BUSY bit is reset to 0).
2. The state of TxRequestEsc changes from INACTIVE to ACTIVE by setting the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 bit field to 1.

10.3.4.4.16.2 DSI Exiting ULPS

To exit ULPS for a clock lane, the following sequence is required:

1. Change the state of TxUlpsExit for each lane to ACTIVE by setting the DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit field to 1.
2. Wait for the ULPSACTIVENOT_ALL1_IRQ interrupt indicating that all lanes with TxUlpsExit active have acknowledged by asserting UlpsActiveNot. This is done by monitoring the DSI_COMPLEXIO_IRQSTATUS[31] ULPSACTIVENOT_ALL1_IRQ status bit.
3. Start the wake-up timer (GP timer).
4. Wait for the time-out.
5. Change the state of the TxUlpsClk signals to INACTIVE for the clock lane by resetting the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 bit field to 0.
6. Reset the DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit to 0.

NOTE: When the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 and DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit fields are both being written to 0, they can be combined into one write. Both bit fields must be read back to confirm they are effective before proceeding.

To exit ULPS for a clock lane, in case the DSI PHY is in OFF state (the DSI protocol engine sends the DSI PHY to OFF state [PWROFF command] by setting DSI_COMPLEXIO_CFG1[28:27] PWR_CMD = 0x0), the sequence is:

1. Change the state of the TxUlpsClk signals to INACTIVE for the clock lane by resetting the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 bit field to 0.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

2. Change the state of TxUlpsExit for clock lane to INACTIVE by resetting the DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit field to 0. This step is necessary only when a PWROFF command (the command for power control of the DSI PHY) is issued while the sequence for exiting is in progress (the TxUlpsExit signal is already in ACTIVE state).

NOTE: When the DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2[9:5] and DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit fields are both being written to 0, they can be combined into one write. Both bit fields must be read back to confirm they are effective before proceeding.

To exit ULPS for a data lane, the following sequence is required:

1. Change the state of TxUlpsExit for each lane to ACTIVE by setting the DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit field to 1.
2. Wait for the ULPSACTIVENOT_ALL1_IRQ interrupt indicating that all lanes with TxUlpsExit ACTIVE have acknowledged by asserting UlpsActiveNot. This is done by monitoring the DSI_COMPLEXIO_IRQSTATUS[31] ULPSACTIVENOT_ALL1_IRQ status bit.
3. Start the application wake-up timer (GP timer).
4. Wait for the time-out.
5. Change the state of the TxRequestEsc signals to INACTIVE for the data lane by resetting the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 bit field to 0.
6. Reset the DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit field to 0.

NOTE: When the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 and DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit fields are both being written to 0, they can be combined into one write. Both bit fields must be read back to confirm they are effective before proceeding.

To exit ULPS for a data lane, in case the DSI PHY is in OFF state (the DSI protocol engine sends the DSI PHY into OFF state by setting DSI_COMPLEXIO_CFG1[28:27] PWR_CMD bit field to 0x0), the sequence is:

1. Change the state of the TxRequestEsc signals to INACTIVE by resetting the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 bit field to 0.
2. Change the state of TxUlpsExit to INACTIVE by resetting the DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit field to 0. This step is necessary only when a PWROFF command is issued while the sequence for exiting is in progress (the TxUlpsExit signal is already in ACTIVE state).

NOTE: When the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 and DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit fields are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

When the sequence for entering or exiting ULPS is started for specific lanes, users must wait for the completion of the sequence before changing the state of the same or other lanes.

10.3.4.4.17 DSI Interrupts

A single interrupt request (IRQ) is generated by each DSI: DSI_IRQ. This interrupt line is merged with another interrupt line from the DISPC_IRQ into a single IRQ. The DSI_IRQ events are generated only for the enabled VC(s). Two registers are used to enable and monitor the DSI interrupt events:

- DSI_IRQENABLE: This register enables and disables interrupt event reporting for the VCs. Each event for the VC is configured in the DSI_VC_IRQENABLE_i register dedicated to the VC number. In addition, it includes 1 bit to enable error reporting for the DSI PHY. The interrupt is triggered when any error is received from the DSI PHY.
- DSI_IRQSTATUS: The register flags which VC(s) have generated an interrupt. Based on the VC number, the DSI_VC_IRQSTATUS_i register indicates the event generating the interrupt. In addition, it

Copyright © 2013, Texas Instruments Incorporated
PRELIMINARY

includes 1 bit for the status of error reporting for the DSI PHY.

Table 10-538 lists the DSI VC interrupt events

Table 10-538. DSI VC Interrupts

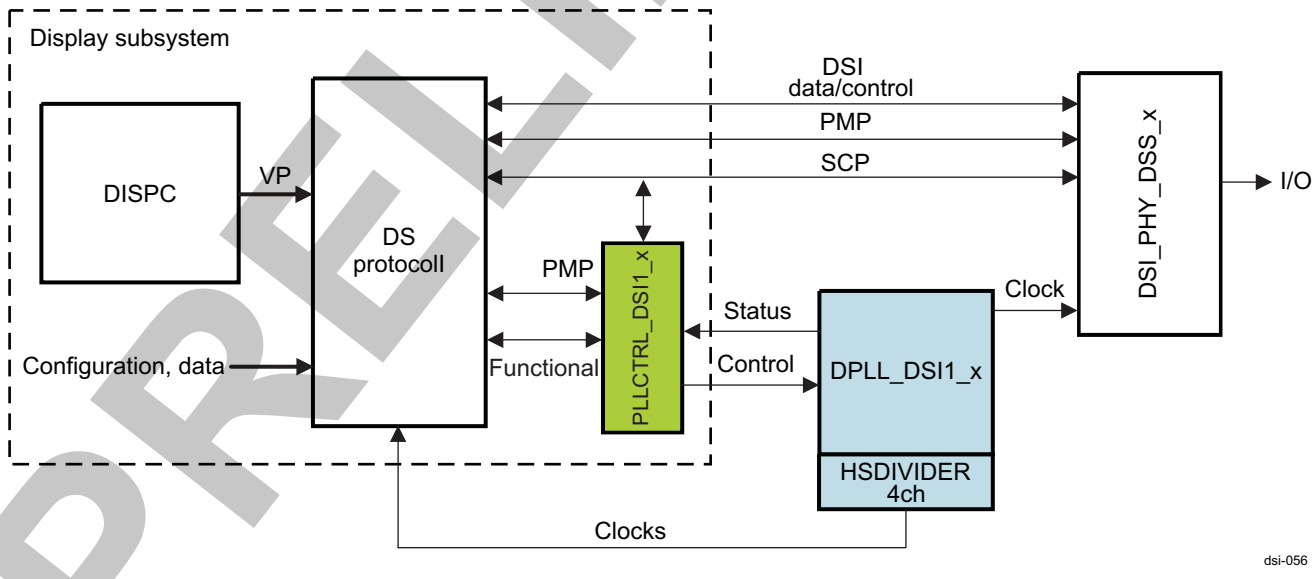
IRQ Name	Description
ECC_CORRECTION_IRQ	Indicates whether a 1-bit error correction has occurred using ECC (short and long packets)
PACKET_SENT_IRQ	Indicates that a packet has been sent. It is used when BTA manual mode is used.
CS_IRQ	Virtual channel. Checksum of the payload mismatch detection.
FIFO_RX_OVF_IRQ	RX FIFO overflow. The FIFO used on the L3_MAIN interconnect slave port for buffering the data received on the DSI link has overflowed.
FIFO_TX_OVF_IRQ	TX FIFO overflow. The FIFO used on the L3_MAIN interconnect slave port for buffering the data received on the interface slave port has overflowed.
BTA_IRQ	BTA is received from the peripheral (the VC ID used for the last BTA request transfer to the peripheral will be used to determine which VC will be used to flag the interrupt).
ECC_NO_CORRECTION_IRQ	ECC error (short and long packets). No correction of the header because of more than 1-bit error.
FIFO_TX_UDF_IRQ	TX FIFO underflow. The FIFO used on the slave port for buffering the data received on the L3_MAIN interconnect slave port has underflowed in the middle of a packet transfer.

10.3.4.5 DSI PLL Controllers

10.3.4.5.1 DSI PLL Controllers Overview

Two DSI PLL controller modules are part of the display subsystem. They use the SCP (see Section 10.3.4.4.6, *Serial Configuration Port Interface*) and power-management port (PMP) as the primary interfaces to the DSI protocol engines. The SCP interface sets the configuration of the digital phase-locked loop (DPLL) and HSDIVIDER modules, primarily the various counter values. The PMP controls the power state of the DPLL and HSDIVIDER modules. Figure 10-144 is an overview of a single DSI PLL controller module in the display subsystem.

Figure 10-144. DSI PLL Controller Overview



NOTE: The DSI PLL controller modules do not have an interface to L3_MAIN interconnect. The programmable features are managed by registers mapped into the DSI protocol engines.

PRELIMINARY

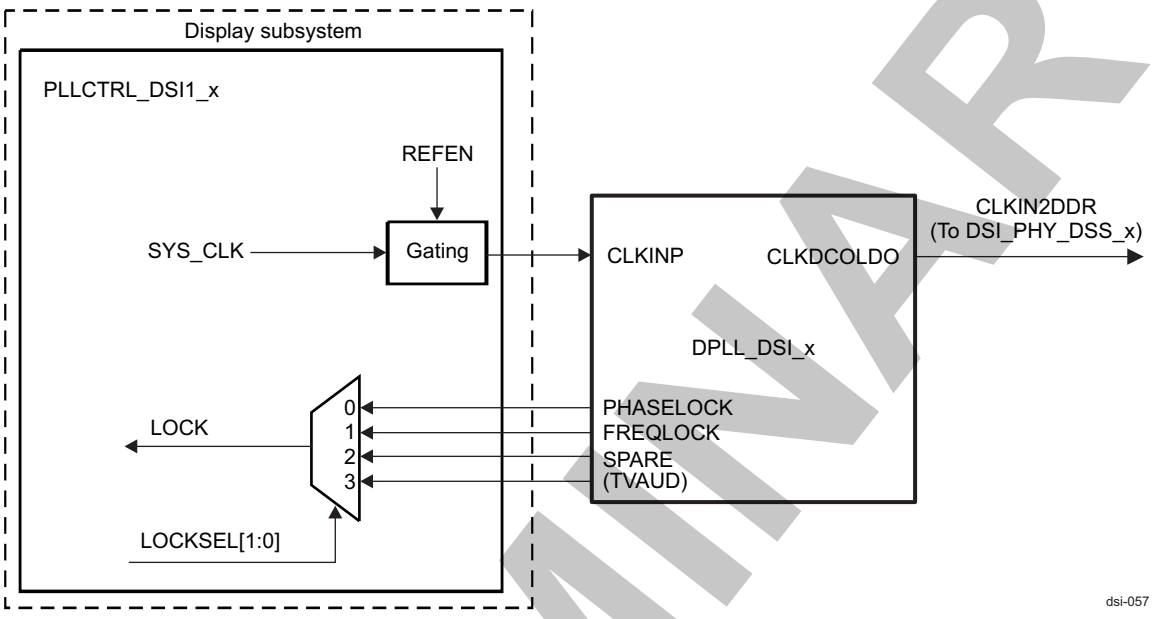
Copyright © 2013, Texas Instruments Incorporated

10.3.4.5.2 DSI PLL Controllers Architecture

The DSI PLLs use type-A instances of the DPLL modules. For information regarding DPLL types, see , *Generic DPLL Overview*, in Chapter 3, PRCM. The pixel clock (PCLK) frequency range is up to 103 MHz.

Figure 10-145 shows the internal reference diagram of a single DSI PLL.

Figure 10-145. DSI PLL Reference Diagram

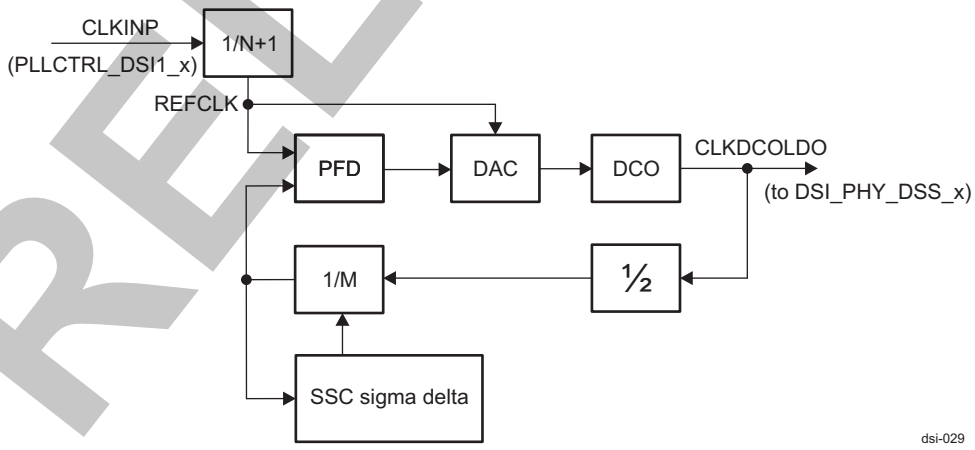


The DSI PLL clock output (CLKDCOLDO) corresponds to the CLKIN2DDR clock of a DSI PHY (DSI_PHY_DSS_x) module.

Only the SYS_CLK clock is used as an input reference clock for the DPLL. The DSI PLL controller can gate this clock by setting the DSI_PLL_CONFIGURATION2[13] PLL_REFEN bit.

Figure 10-146 is a simplified block diagram of the ADPLLM instance used for the DSI modules.

Figure 10-146. DSI DPLL Functional Block Diagram



The input clock CLKINP goes to a predivider N + 1. The entire loop runs on the REFCLK clock after this predivider. The value of N + 1 is controlled through the DSI_PLL_CONFIGURATION1[8:1] PLL_REGN bit field. The frequency range for the CLKINP and REFCLK clocks is as below:

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 10-539. DSI PLL CLKINP and REFCLK frequency range

Clock	Type	Min Frequency	Max Frequency
CLKINP	Input	0.032MHz	52MHz
REFCLK when DSI_PLL_CONFIGURATION2[5] PLL_PLLLPMODE	Input	0.15MHz	52MHz
REFCLK when DSI_PLL_CONFIGURATION2[5] PLL_PLLLPMODE	Input	0.032MHz	1MHz

The output clock CLKDCOLDO is synthesized by a digitally controlled oscillator (the DCO block) that automatically detects the frequency range. The CLKDCOLDO frequency can be given with CLKDCOLDO = CLKINP * 2 * M / (N + 1). For that purpose the feedback multiplier M must be configured through the DSI_PLL_CONFIGURATION1[20:9] PLL_REGM bit field.

The DPLL module also supports spread spectrum clocking (SSC) on its output clocks. SSC is used to spread the spectral peaking of the clock to reduce electromagnetic interference (EMI). When SSC is enabled, the clock spectrum is spread by the amount of frequency spread, and the attenuation is given by the ratio of the frequency spread (df) and the modulation frequency (fm), that is, $[\{10*\log_{10}(df/fm)\} - 10]$ dB.

The SSC is performed by changing the feedback divider (M) in a triangular pattern, which means the frequency of the output clock varies in a triangular pattern. The frequency of the triangular pattern is modulation frequency (fm). The peak (dM) or the amplitude of the triangular pattern as a percent of M is equal to the percent of the frequency spread (df) (that is, dM / M = df / Fout).

Since this is in band modulation for the DSI PLL, the modulation frequency (fm) is required to be within the bandwidth of the PLL loop (lowest BW of REFCLK/70; that is, REFCLK must be > fm*70). A higher modulation frequency results in less spreading in the output clock.

The SSC can be enabled and disabled by asserting the DSI_PLL_SSC_CONFIGURATION1[0] EN_SSC bit. The acknowledge signal SSCACK, observed by the DSI_PLL_STATUS[12] SSC_EN_ACK bit, notifies the exact start and end of SSC. When EN_SSC is deasserted, SSC is disabled only after completion of one full cycle of the triangular pattern given by the modulation frequency. This is done to maintain the average frequency.

The modulation frequency (fm) can be programmed as a ratio of REFCLK/4; that is, the value of ModFreqDivider programmed in the DSI_PLL_SSC_CONFIGURATION2[29:20] MODFREQDIVIDER bit field must be = REFCLK / (4 * fm). The ModFreqDivider is split into Mantissa and $2^{Exponent}$(ModFreqDivider = ModFreqDividerMantissa *$2^{ModFreqDividerExponent}$).

- The Mantissa is controlled by bits [29:23] of the MODFREQDIVIDER bit field.
- The Exponent is controlled by bits [22:20] of the MODFREQDIVIDER bit field.

Although the same value of ModFreqDivider could be obtained by different combinations of Mantissa and Exponent values, it is preferred to get the target ModFreqDivider by programming maximum Mantissa and minimum Exponent values.

To define the frequency spread (df), M must be controlled as previously explained. To define M, the step size of M for each REFCLK during the triangular pattern bust be programmed (that is, M = ModFreqDivider * DeltaMStep). DeltaMStep is controlled by the DSI_PLL_SSC_CONFIGURATION2[19:0] DELTAM bit field and the PLL_SSC_CONFIGURATION2[30] DELTAM2 bit. DeltaMStep is split into an integer part and a fractional part:

- The integer part is controlled by bits [19:18] of the DELTAM bit field.
- The fractional part is controlled by bits [17:0] of the DELTAM bit field.The frequency spread achieved, however, has an overshoot of 20% or an inaccuracy of +20%.

If the DSI_PLL_SSC_CONFIGURATION1[2] DOWNSPREAD bit is set to 1, the frequency spread on the lower side is twice the programmed value. The frequency spread on the higher side is 0 (except for the overshoot, as previously described).

NOTE: There is a restriction in the range of M values. The restriction is that (M – dM) must be >= 20.Also, M + dM should be <= 2045. If the DSI_PLL_SSC_CONFIGURATION1[2] DOWNSPREAD bit is set to 1, then (M – 2*dM) should be >= 20 and M <= 2045.

PRELIMINARY

10.3.4.5.3 DSI PLL Operations

The DSI PLL configuration signals operate according to Table 10-540, which indicates the operation when the PLLs are not locked.

Table 10-540. DSI PLL Operation Modes When Not Locked

DSI PLL Operation Mode	Stop Mode Low Power[1]	Stop Mode Fast Relock[1]	Idle Bypass
Mode Description	Output clocks stopped Lowest power standby	Output clocks stopped Fastest start-up time	Selects when PLL and HSDIVIDER bypass clocks are used
DSI_PLL_CONFIGURATION2[0] PLL_IDLE	0	0	1
DSI_PLL_CONFIGURATION2[6] PLL_LOWCURRSTBY	1	0	1

(1) This mode must be used for better performance.

When locked, the PLL output frequency is: Input frequency × 2 × M / (N + 1), where:

- M multiplier is programmed in the DSI_PLL_CONFIGURATION1[20:9] PLL_REGM bit field.
- N divider is programmed in the DSI_PLL_CONFIGURATION1[8:1] PLL_REGN bit field.

NOTE: When the PLL_REGM bit-field is set to 1, the PLL enters a MN-Bypass mode. This is a low power mode, where the PLL gates its internal clocks and powers down the analog blocks. The CLKDCOLDO clock output goes low and remains like that, until the PLL comes out of the MN-Bypass mode (by changing the PLL_REGM bit-field to a value other than 0 or 1).

10.3.4.5.4 DSI PLL Controllers Shadowing Mechanism

The configuration registers are accessed through the DSI protocol engine register spaces using the SCP interface. This includes all the configuration signals and returning status signals.

CAUTION

All writes must be 32-bit operations, because the SCP interface always transfers 32 bits; 16- or 8-bit operations may lead to unpredictable errors.

A shadow mechanism is implemented for appropriate register values so that configurations can optionally be updated in synchronization with the DISPC and DSI protocol engines. The front porch time from the DISPC indicates the time when making the update of the value. All the required updated values must be written before this signal is asserted. For more information, see Section 10.3.4.4.6.1, *Shadowing Register*.

10.3.4.5.5 DSI PLL Error Handling

The PLL lock and recalibration signals can be monitored to detect the loss of lock or the requirement to recalibrate (caused by a large temperature change since the last lock request):

- The DSI_PLL_STATUS[1] PLL_LOCK status bit gives the DSI PLL lock state.
- The DSI_PLL_STATUS[2] PLL_RECAL status bit informs whether the PLL must be uncalibrated.

These signals can also generate interrupts at the DSI protocol engine level:

- The PLL_LOCK_IRQ interrupt indicates that the DSI PLL control module has sent a lock request to the DSI PLL. To monitor this event, read the DSI_IRQSTATUS[7] PLL_LOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_UNLOCK_IRQ interrupt indicates that the DSI PLL control module has sent an unlock request to the DSI PLL. To monitor this event, read the DSI_IRQSTATUS[8] PLL_UNLOCK_IRQ bit. Set this bit to 1 to clear the status bit.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- The PLL_RECAL_IRQ interrupt indicates that the DSI PLL control module has sent a recalibration request to the DSI PLL. To monitor this event, read the DSI_IRQSTATUS[9] PLL_RECAL_IRQ bit. Set this bit to 1 to clear the status bit.

The PLL reference loss and limp status signals can also be monitored:

- The DSI_PLL_STATUS[3] PLL_LOSSREF status bit informs whether the DSI PLL has lost the reference.

10.3.4.5.6 DSI PLL Software Reset

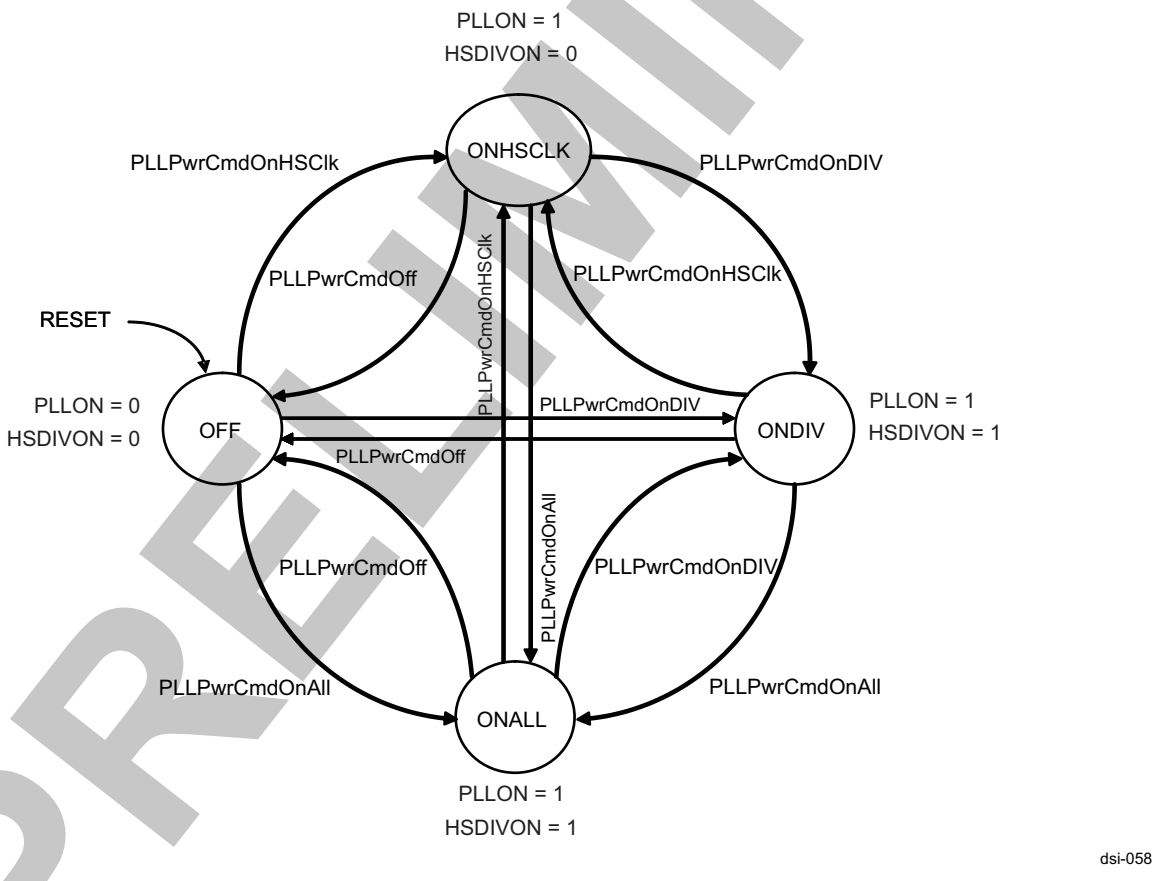
The DSI PLL control modules do not have their own software reset. They are reset by the global DSS_RST signal at PRCM module level. See Display Subsystem Resets, in *Display Subsystem*. Nevertheless, software users can monitor the reset statuses of the DSI PLL control modules by reading the DSI_PLL_STATUS[0] PLLCTRL_RESET_DONE status bits.

10.3.4.5.7 DSI PLL Power Management

PLLCTRL manages only the LDO power of the DPLL and HSDIVIDER; this is done by overriding the SYSRESET signals. All other power-management signals are integrated with the display subsystem power management.

Figure 10-147 shows the power states that are controlled through the PMP.

Figure 10-147. DSI PLL Power State Diagram



PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

10.3.4.5.8 DSI PLL HSDIVIDER Loading Operation

In manual mode (PLL_CONTROL[0] PLL_AUTOMODE = 0), it is possible to update the configuration values of HSDIVIDER without starting the DPLL locking sequence. Once all the configuration values have been programmed into the registers, the PLL_GO[1] HSDIVLOAD bit must be set. The TENABLEDIV output is driven high for six SCP clock periods while the TINITZ and TENABLE signals remain unchanged. The HSDIVLOAD bit is cleared at the end of the sequence.

The TENABLEDIV signal is shared with the DPLL and HSDIVIDER so the DPLL M2 divider is loaded at the same time. The SCPBUSY signal is high during the sequence until the HSDIVLOAD bit is cleared, thus indicating that there is pending activity in the SCPClk domain. SCPClk must be kept running while this signal is asserted.

The HSDIVIDER sequence and the GO sequence (Section 10.3.4.5.11, *DSI PLL Go Sequence*) cannot be performed at the same time. If one of the two sequences is running and the trigger bit of the other sequence is set, PLLCTRL finishes the first sequence and then immediately starts the other sequence.

10.3.4.5.9 DSI PLL Clock-Gating Sequence

Clock gating can be used to reduce system power consumption when the DSI protocol engine indicates that it does not need the clock. If the HSDIVIDER is not used, the PLL can also be stopped (at the cost of additional unstarting latency).

The DSI protocol engines must verify when the PLLs have restarted by inspecting the LOCK signal (the DSI_PLL_STATUS[1] PLL_LOCK status bit), because the TXBYTECLKHS clocks are stopped when the CLKIN2DDR clocks generated by the DSI PLL are stopped. This eliminates the need for any explicit feedback that the clock has restarted. This flow chart shown in Figure 10-148 should run even if the DSI_PLL_GO[0] PLL_GO bit is not set.

Figure 10-148 shows the DSI PLL gated mode sequence.

10.3.4.5.10 DSI PLL Clock Sequence

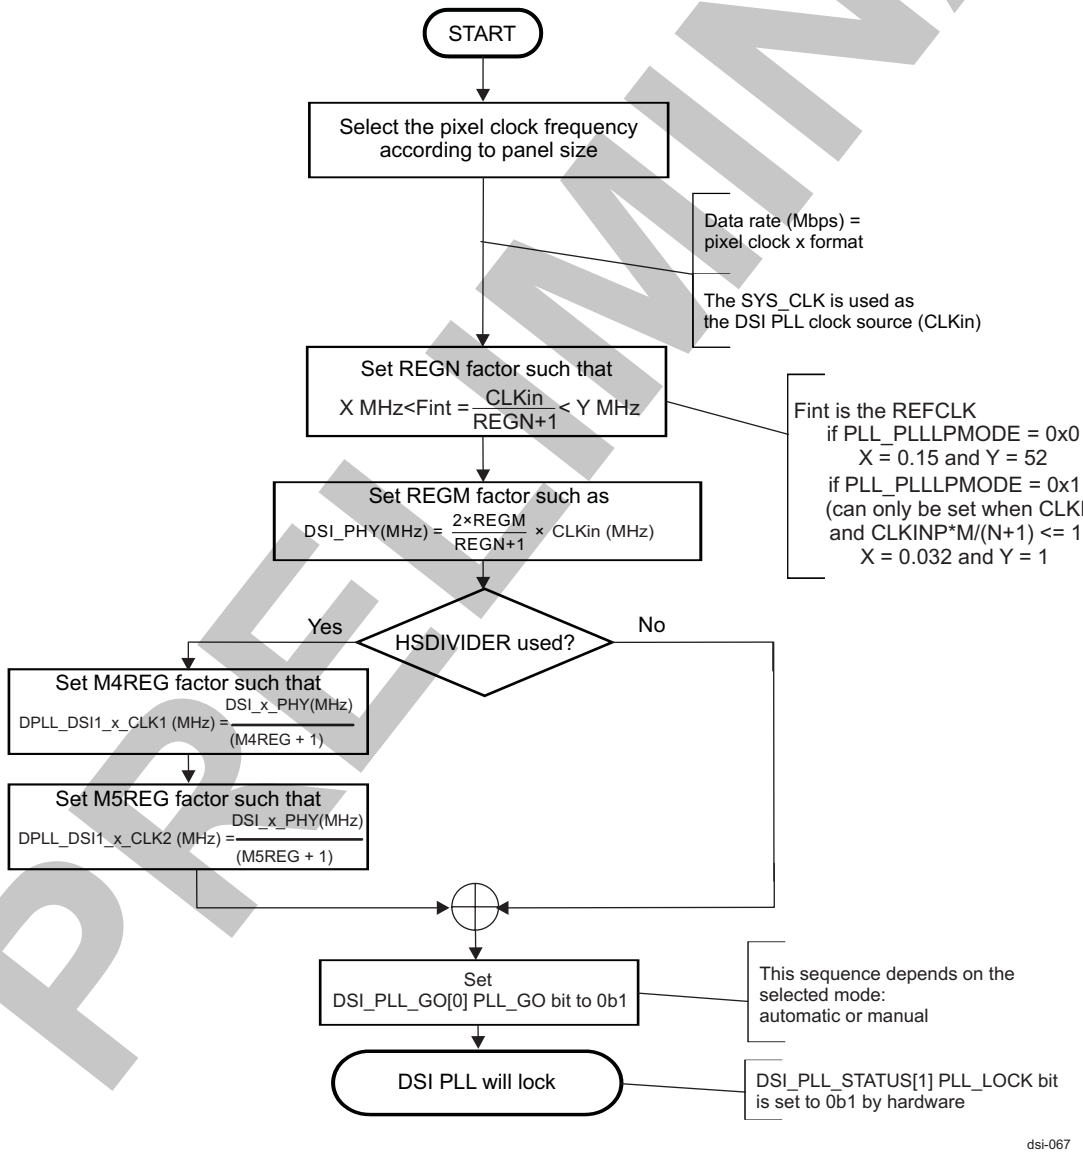
The two DSI PLLs generate the CLKIN2DDR clocks. Each HSDIVIDER outputs two clocks: DPLL_DSI1_x_CLK1, connected to the DISPC, and DPLL_DSI1_x_CLK2, connected to the DSI protocol engine (where x is the dedicated DSI PLLs [A or C]). If these two clocks are not used, the HSDIVIDER functions are not required.

The CLKIN2DDR clocks are twice the DSI output clock frequency, which is equal to the data rate. The DSI PLL factors must be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency in the appropriate range:

- REGM factor is programmed by the DSI_PLL_CONFIGURATION1[20:9] PLL_REGM bit field.
- REGN factor is programmed by the DSI_PLL_CONFIGURATION1[8:1] PLL_REGN bit field.
- M4REG factor is programed by the DSI_PLL_CONFIGURATION1[25:21] M4_CLOCK_DIV bit field, and applies to DPLL_DSI1_x_CLK1.
- M5REG factor is programmed by the DSI_PLL_CONFIGURATION1[30:26] M5_CLOCK_DIV bit field, and applies to DPLL_DSI1_x_CLK2.

Figure 10-149 shows the programming sequence.

Figure 10-149. DSI PLL Programming Sequence



PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE:

- The M4REG and M5REG factors must be set respecting the following conditions:
  - The DPLL_DSI1_x_CLK1 frequency must be a multiple of PCLK frequency (for proper settings of the PCD and LCD factors in the DISPC).
  - The DPLL_DSI1_x_CLK1 and DPLL_DSI1_x_CLK2 frequencies must be lower than 200 MHz. For more information about clock frequency ratings, see Display Subsystem Clocks, in Chapter 10, *Display Subsystem*.
- Most of the other DSI PLL programming values are available for software flexibility, but it is not recommended to update the values in normal use. For the recommended DSI PLL values, see Section 10.3.4.5.12, *DSI PLL Recommended Values*.

Table 10-542. DSI Register Call Summary for DSI PLL Programming Sequence

Register Name	Register Name	Register Name
DSI_PLL_CONFIGURATION2	DSI_PLL_GO	DSI_PLL_STATUS

10.3.4.5.11 DSI PLL Go Sequence

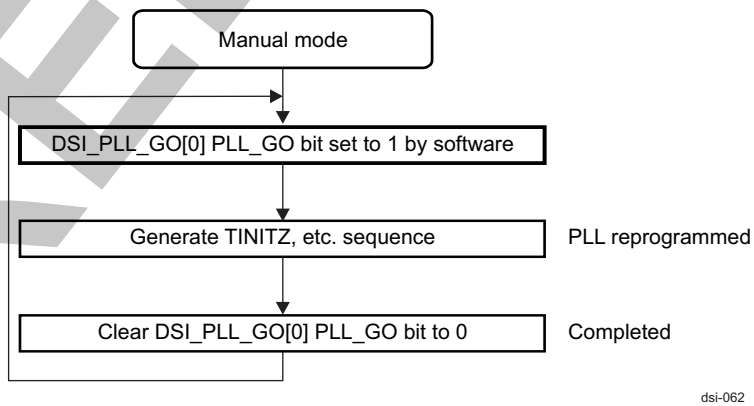
In manual mode (the DSI_PLL_CONTROL[0] PLL_AUTOMODE bit is set to 0), the DPLL requires a sequence on TINITZ, TENABLE, and TENABLEDIV to update the configuration values and start the locking sequence.

When all the configuration values are programmed into the registers, the GO bit must be set. The appropriate sequence is then sent on the TINITZ, TENABLE, and TENABLEDIV pins, respecting the timing requirements of the DPLL. The DSI_PLL_GO[0] PLL_GO bit is cleared to 0 at the end of the sequence.

The TENABLEDIV signal is shared with the HSDIVIDER module so that it is programmed at the same time. In this mode, software must deassert CLKINEN by setting the DSI_PLL_CONFIGURATION2[14] PHY_CLKINEN bit to 0 and assert HSDIVBYPASS correctly by setting the DSI_PLL_CONFIGURATION2[20] HSDIVBYPASS bit to 1 to prevent uncontrolled frequencies affecting DSI_PHY_DSS_x and the display subsystem during PLL locking. In manual mode, the shadow register is updated anyway so that valid values are present when later selecting automatic mode.

Figure 10-150 shows the DSI PLL Go flow chart in manual mode (the DSI_PLL_CONTROL[0] PLL_AUTOMODE bit is set to 0).

Figure 10-150. DSI PLL Go Sequence (Manual Mode)



NOTE: All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

PRELIMINARY

In automatic mode (the DSI_PLL_CONTROL[0] PLL_AUTOMODE bit is set to 1), the TINITZ, TENABLE, and TENABLEDIV sequence and the update of the PLL configuration from the DSI_PLL_CONFIGURATION2 register are deferred until the time of the front porch time signal sent by the DISPC module. This is intended to simplify the software to implement a configuration change (such as a frequency change to support a different link bandwidth). In this mode, CLKINEN, HSDIVBYPASS, and REFEN are automatically controlled and the register value is overridden.

Figure 10-151 shows the DSI PLL Go flow chart in automatic mode (the DSI_PLL_CONTROL[0] PLL_AUTOMODE bit is set to 1).

10.3.4.5.12 DSI PLL Recommended Values

Table 10-544 shows the DSI PLL recommended values.

Table 10-544. DSI PLL Recommended Programming Values

Field Name	Value	Description
DSI_PLL_CONTROL[4] HSDIV_SYSRESET	0	Allow power FSM to control
DSI_PLL_CONTROL[3] PLL_SYSRESET	0	Allow power FSM to control
DSI_PLL_CONTROL[2] PLL_HALTMODE	–	For information, see Section 10.3.4.5.9, *DSI PLL Clock-Gating Sequence*.
DSI_PLL_CONTROL[1] PLL_GATEMODE	–	For information, see Section 10.3.4.5.9, *DSI PLL Clock-Gating Sequence*.
DSI_PLL_CONTROL[0] PLL_AUTOMODE	–	For information, see Section 10.3.4.5.9, *DSI PLL Clock-Gating Sequence*.
DSI_PLL_GO[0] PLL_GO	1–>0	Write 1 when PLL is to be (re)locked with new parameters. This bit is cleared by hardware when the PLL request completes.
DSI_PLL_CONFIGURATION1[30:36] M5_CLOCK_DIV	See (1).	DSI protocol engine clock divider
DSI_PLL_CONFIGURATION1[25:21] M4_CLOCK_DIV	See (1).	DSS clock divider
DSI_PLL_CONFIGURATION1[20:9] PLL_REGM	See (1).	Feedback clock divider
DSI_PLL_CONFIGURATION1[8:1] PLL_REGN	See (1).	Reference clock divider
DSI_PLL_CONFIGURATION2[20] HSDIVBYPASS	0	PLL controls HSDIVIDER bypass
DSI_PLL_CONFIGURATION2[18] M5_CLK_EN	1	If PLL/HSDIVIDER is used as the DSI protocol clock source
DSI_PLL_CONFIGURATION2[16] M4_CLOCK_EN	1	If PLL/HSDIVIDER is used as the clock source
DSI_PLL_CONFIGURATION2[15] BYPASSEN	0	To use PLL as the clock source. For small displays, it may be possible to use the display subsystem functional clock, DSS_CLK, in which case this bit must be set to 1. See Section 10.3.4.2, *DSI Clock Configuration*.
DSI_PLL_CONFIGURATION2[14] PHY_CLKINEN	1	Enable CLKIN2DDR clock
DSI_PLL_CONFIGURATION2[13] PLL_REFEN	1	Enable PLL reference
DSI_PLL_CONFIGURATION2[10:9] PLL_LOCKSEL	0x0	Phase lock criteria to lock the PLL
DSI_PLL_CONFIGURATION2[8] PLL_DRIFTGUARDEN	0x0	The RECAL status/interrupt must be used to decide when to perform a PLL uncalibration. No automatic uncalibration is performed.
DSI_PLL_CONFIGURATION2[6] PLL_LOWCURRSTDBY	0/1	Set to 0 for fast PLL unlock, but higher standby current. Set to 1 for leakage level standby current, but longer unlock time.
DSI_PLL_CONFIGURATION2[5] PLL_PLLLPMODE	0	Normal operation. For smaller display sizes, it may be possible to set to 1.
DSI_PLL_CONFIGURATION2[0] PLL_IDLE	0	PLL active

(1) The value of the bit field must be set according to the desired clock frequency.

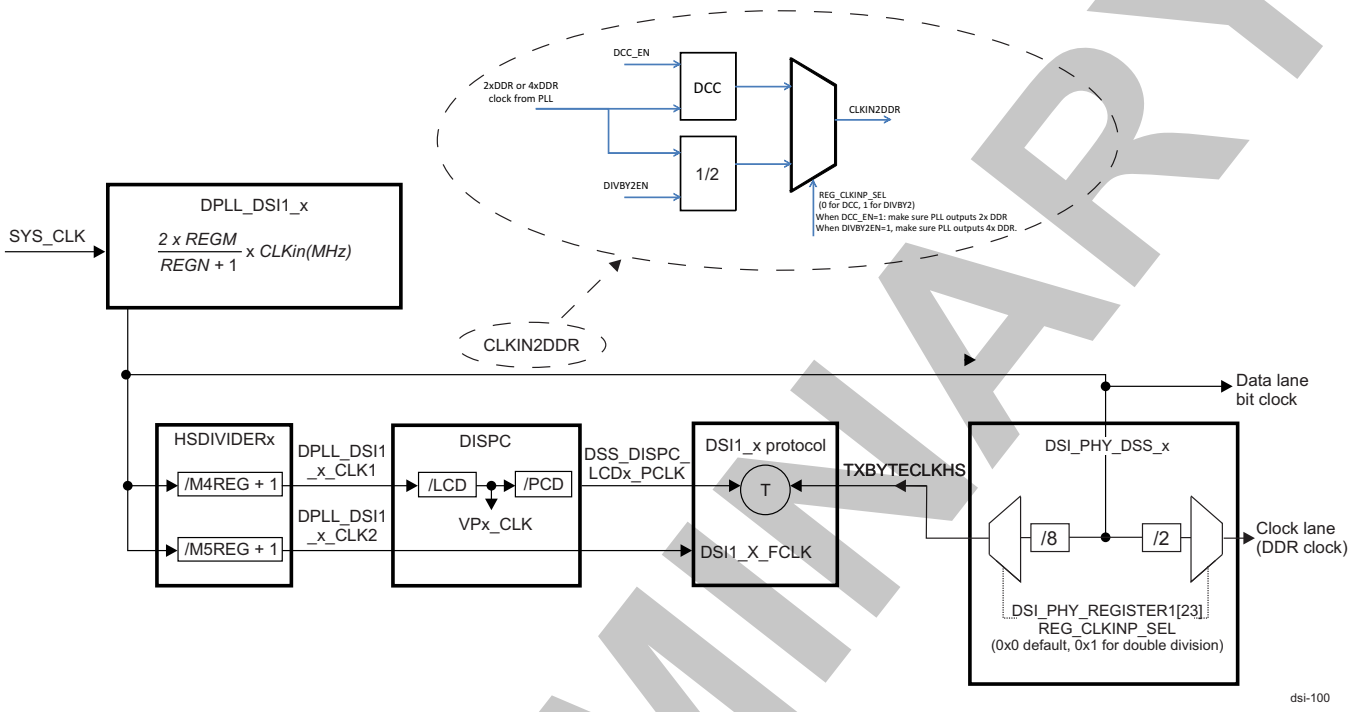
10.3.4.5.13 DSI How to Configure the DSI PLL in Video Mode

Figure 10-152 is a global overview of the DSI1_A and DSI1_C clock trees when used in video mode.

Figure 10-152. DSI Clock Tree in Video Mode



The settings of the DSI PLL registers can be summarized by the following equations.

Equation 1

$$N \times T_{VP_CLK} = T_L \times T_{TXBYTECLKHS}$$

dsi-e101

where

- $T_L = T_{HS} + HSA_{DSI} + T_{HE} + HFP_{DSI} + ceiling((WC + 6) / NDL) + HBP_{DSI}$
- N is an integer.
- NDL: Number of data lanes
- WC: Word count or payload in bytes
- HSA_{DSI} is HSA period in video mode.
- HBP_{DSI} is HBP period in video mode.
- HFP_{DSI} is HFP period in video mode.

T_{HS} is the length of HSYNC start short packet in the number of byte clock cycles (TXBYTECLKHS).

- The generation of this packet can be enabled by setting the DSI_CTRL[17] VP_HSYNC_START bit to 1.
- T_{HS} is equal to ceiling(4 / NDL), if VP_HSYNC_START = 1; else, it is 0.

T_{HE} is the length of HSYNC end short packet in the number of byte clock cycles (TXBYTECLKHS).

- The generation of this packet can be enabled by setting the DSI_CTRL[18] VP_HSYNC_END bit to 1.
- T_{HE} is equal to 1, if (VP_HSYNC_START = 1, VP_HSYNC_END = 1, HSA_{DSI} = 0, and NDL = 3), else
- T_{HE} is equal to ceiling(4 / NDL), if (VP_HSYNC_START = 1 and VP_HSYNC_END = 1); else, it is 0.

NOTE: HSA_{DSI} timing is not used and does not have to be programmed when HE short packet is not generated.

Equation 2

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

$$R = T_{TXBYTECLKHS} / T_{VP_PCLK}$$
dsi-e102

To synchronize the DISPC and DSI protocol engines, users must follow the ratio R between TXBYTECLKHS and VP_PCLK, as listed in Table 10-545.

Table 10-545. DSI Ratio R

Number of Data Lanes (Up to 4 Data Lanes for DSI1_A and DSI1_C)	Pixel Format	Ratio R
1	16-bit pixel	1/2
1	18-bit pixel	4/9
1	24-bit pixel	1/3
2	16-bit pixel	1
2	18-bit pixel	8/9
2	24-bit pixel	2/3
3	16-bit pixel	3/2
3	18-bit pixel	4/3
3	24-bit pixel	1
4	16-bit pixel	2
4	18-bit pixel	16/9
4	24-bit pixel	4/3

All cases are covered by:

$$F_{VP_PCLK} \times bits_per_pixel = F_{TXBYTECLKHS} \times NDL \times 8$$
dsi-e110

NOTE: Table 10-545 defines the strict ratio values to be used for no line buffer configuration (where DSI burst mode is not supported).

In case of two (or one) line buffers configuration (where DSI burst mode is supported), the ratio R = TTXBYTECLKHS / TVP _PCLK is not limited to the values in Table 10-545. It can be set to other values by ensuring that the line lengths on DISPC and DSI match Equation 3.

Equation 3

$$(HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) \times T_{VP_PCLK} = (4/NDL + HFP_{DSI} + (WC+6)/NDL + HBP_{DSI}) \times T_{TXBYTECLKHS}$$
dsi-e103

Equation 4

$$HFP_{DSI} = ((HFP_{DISPC} \times bits_per_pixel)/(NDL \times 8)) - (2/NDL)$$
dsi-e109

Example

The desired performances are:

- Clock lane at 150 MHz
- RGB24-888
- 1-data lane
- LCD size 480 × 640 with $HSA_{DISP} = HFP_{DISP} = HBP_{DISP} = 20$, $VSA_{DISP} = VFP_{DISP} = VBP_{DISP} = 2$

Step 1. Determine REGM and REGN.

To obtain correct stability, F_{int} must be kept between 0.032 MHz and 52 MHz. In this case, F_{int} is maintained at 2 MHz. For more information, see Section 10.3.4.5.2, *DSI PLL Controllers Architecture*, Section 10.3.4.5.10, *DSI PLL Clock Sequence*, and Section 10.3.5.2.1.1, *Main Sequence – DSI PLL*

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Setup.

$$REGN = (F_{SYS_CLK} / F_{int}) - 1$$
$$REGN = 12$$
$$REGM = (REGN + 1) \times F_{CLKIN2DDR} / (2 \times F_{SYS_CLK})$$
$$REGM = 75$$

dsi-e113

where

- SYS_CLK = 26 MHz is used as a reference clock.

Step 2. Determine VP_PCLK and TXBYTECLKHS clocks.

TXBYTECLKHS frequency is equal to 37.5 MHz. With ratio R equal to 1/3, VP_PCLK frequency is equal to 12.5 MHz. The frame rate can be estimated by:

$$\text{Frame rate} = F_{VP_PCLK} / (HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) \times (VSA_{DISPC} + LPP + VBP_{DISPC})$$
$$\text{Frame rate} = 12.5\ \text{MHz} / (540) \times (646)$$
$$\text{Frame rate} = 35.83\ \text{frame/sec}$$

dsi-e123

Step 3. Determine LCD, PCD, and M4REG.

$$T_{CLKIN2DDR} = T_{TXBYTECLKHS}/8 = T_{DSS_DISPC_LCDx_PCLK}/((M4REG + 1) \times LCD \times PCD)$$
$$((M4REG + 1) \times LCD \times PCD) = 8 \times 3$$

dsi-e115

If LCD and PCD are set to 1 and 3, respectively, M4REG is equal to 7.

Step 4. Verify N as integer.

First, TL must be determined:

$$(HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) \times T_{VP_PCLK} / T_{TXBYTECLKHS} = T_L = 1620$$

dsi-e116

From **Equation 1** follows:

$N \times T_{VP_CLK} = T_L \times T_{TXBYTECLKHS}$

$N = T_{TXBYTECLKHS} \times T_L / T_{VP_CLK} = T_L / (R \times PCD)$

$N = 14580$

N is an integer.

Step 5. Determine HFP and HBP of the DSI protocol engine.

From **Equation 3** follows:

$$((HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) \times T_{VP_PCLK} / T_{TXBYTECLKHS}) - (4/NDL + (WC + 6)/NDL) = HFP_{DSI} + HBP_{DSI}$$
$$HFP_{DSI} + HBP_{DSI} = 170$$

dsi-e117

From **Equation 4** follows:

$$HFP_{DSI} = ((HFP_{DISP} \times bits_per_pixel)/NDL \times 8)) - (2/NDL)$$
$$HFP_{DSI} = 58$$
$$HBP_{DSI} = 170 - 58 = 112$$

dsi-e121

10.3.4.6 DSI PHY

10.3.4.6.1 DSI PHY Overview

DSI_PHY_DSS_x is a DSI PHY with five unidirectional (HS) lane modules. This includes four data lane modules and one clock lane module. Each lane module has two data pads (DX, DY). These data pads are connected with a complementary lane module on the DSI receiver device using a point-to-point interconnect.

Lane modules support HS burst mode. Forward direction and reverse direction escape modes are also supported. Escape modes can be used for low-power data transmission, among other things.

The maximum data rate supported in HS mode is 1 Gbps for up to four data lanes. The lane module function and position are configurable; that is, any lane module can be chosen as a clock lane module, and the DX/DY data pad for each lane module can be configured as a DP or DN pin defined by the D-PHY specification.

DSI_PHY_DSS_x interacts with the higher layers of the DSI link through the PPI. DSI_PHY_DSS_x does not include a PLL; a high-frequency clock input is expected in HS mode (CLKIN2DDR). DSI_PHY_DSS_x also supports the SCP interface to set various configuration and control registers.

10.3.4.6.2 DSI PHY Software Reset

The clock domain using the TXBYTECLKHS byte clock from the DSI PHY has dedicated reset-done information in the DSI_COMPLEXIO_CFG1[29] RESET_DONE bit. The DSI_SYSCONFIG[1] SOFT_RESET bit is used to reset the byte clock power domain. A dummy read using the SCP interface to any DSI_PHY_DSS_x register is required after DSI_PHY_DSS_x reset to complete the reset of the DSI PHY.

10.3.4.6.3 DSI PHY Reset-Done Bits

The DSI PHY has several clock domains. The reset status for each clock domain is provided in the DSI_PHY_REGISTER5 register:

- DSI_PHY_REGISTER5[31] RESETDONETXBYTECLK bit: Reset done for the TXBYTECLK domain.
- DSI_PHY_REGISTER5[28:24] RESETDONETXCLKESCi bit field: Reset done for the TXCLKESC domain for lane i (where i = 0 to 4).
- DSI_PHY_REGISTER5[30] RESETDONESCPCLK bit: Reset done for the SCP clock domain. Software users must perform a dummy read on this bit to initiate the reset sequence of the SCP FSM. When the reset sequence completes, the RESETDONESCPCLK signal goes high, and software users can read again the DSI_PHY_REGISTER5[30] RESETDONESCPCLK bit to ensure that the value is now 1.

  NOTE: Software must not write in the DSI_PHY_DSS_x SCP registers before the DSI_PHY_REGISTER5[30] RESETDONESCPCLK bit is set to 1.

- DSI_PHY_REGISTER5[29] RESETDONEPWRCLK bit: Reset done for the PWR clock domain. The reset sequence of the PWR FSM is complete when the RESETDONEPWRCLK signal goes high.

10.3.4.6.4 DSI PHY Pad Configuration

The number of lanes is configurable through the DSI_COMPLEXIO_CFG1 register.

It is not allowed to change:

- The position on the fly (by modifying DATAx_POSITION, where x = 1 through 4, and CLOCK_POSITION fields)
- The P/N order (positive/negative order of the differential pair by modifying DATAy_POL, where y = 1 through 4, and CLOCK_POL)
- The number of active data lanes (by modifying the DSI_COMPLEXIO_CFG1[10:8] DATA2_POSITION, DSI_COMPLEXIO_CFG1[14:12] DATA3_POSITION, and DSI_COMPLEXIO_CFG1[18:16]

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

DATA4_POSITION bit fields).

To add or remove the second, third, or fourth lanes, the DSI PHY must be in off mode.

The configuration of the DSI PHY (number of data lanes, position, differential order) must not be changed while the DSI_CLK_CTRL[20] LP_CLK_ENABLE bit is set to 1. For hardware to recognize a new configuration of the DSI PHY (done in the DSI_COMPLEXIO_CFG1 register), the following sequence must be followed. If the sequence is not followed, the DSI PHY configuration is undetermined.

1. Set the DSI_CTRL[0] IF_EN bit to 1.
2. Reset the DSI_CTRL[0] IF_EN bit to 0.
3. Set the DSI_CLK_CTRL[20] LP_CLK_ENABLE bit to 1.
4. Set the DSI_CTRL[0] IF_EN bit again to 1.

The minimum requirement for the number of lanes is one clock lane and one data lane. By default, the second, third, and fourth data lanes are not connected (the reset value of the DATAx_POSITION bit field is 0).

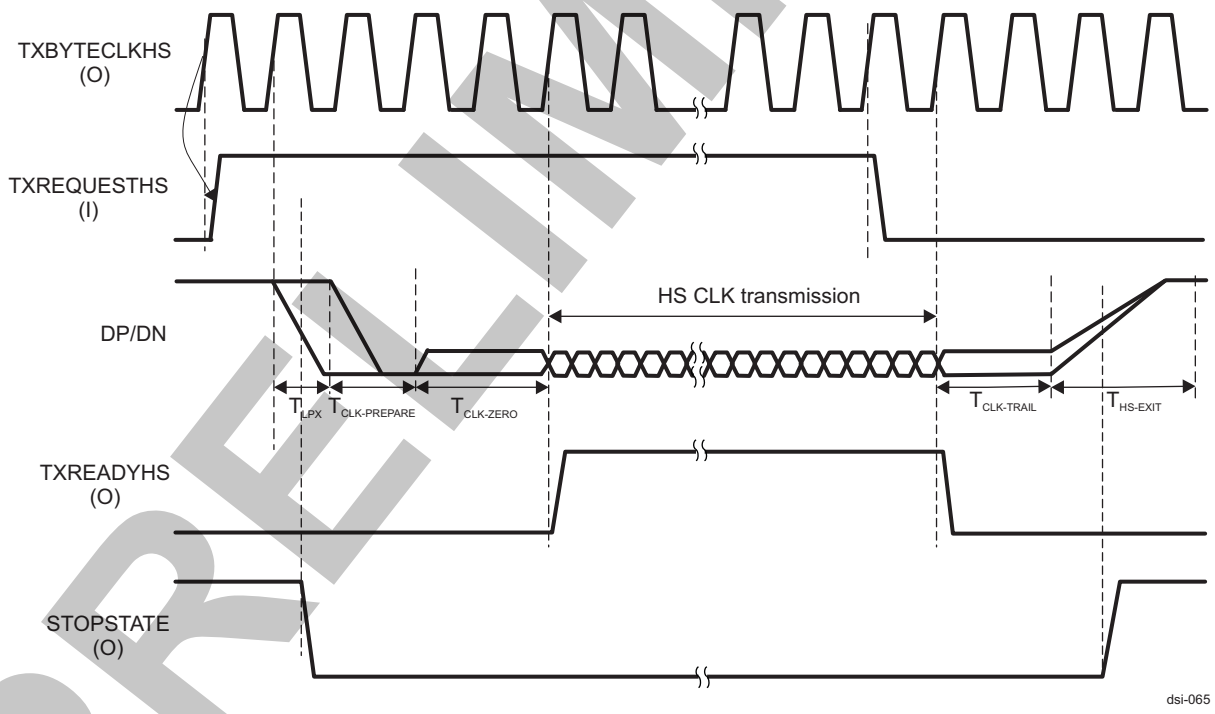
10.3.4.6.5 DSI PHY Display Timing Configuration

Depending on the CLKIN2DDR clock frequency settings programmed with the DSI PLL control module, software users must program accordingly the timing parameters in the DSI PHY registers.

10.3.4.6.5.1 DSI PHY HS Clock Transmission

Figure 10-153 shows an example of HS clock transmission.

Figure 10-153. DSI PHY HS Clock Transmission



TXBYTECLKHS is an output clock derived by dividing CLKIN2DDR by 8.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: DSI_PHY_DSS_X can work with 2x DDR from PLL, compared to the 4x clock required in previous devices. The slower clock requirement saves power inside PLL and PHY. A duty cycle corrector (DCC) is used inside PHY to correct the duty cycle and allow use of 2x clock. 4x clock mode (legacy) is also supported. The default setting for the PHY is 2x clock. The 2x clock is only supported from data rate of 500Mbps to 1,255.5 Mbps. Below 500Mbps data rates, the DCC must be bypassed and PLL be programmed to 4x clock.

The TXBYTECLKHS clock is driven by DSI_PHY_DSS_x when:

- CLKIN2DDR is running and the DSI_PLL_CONFIGURATION2[14] PHY_CLKINEN bit is set to 1.
- DSI_PHY_DSS_x is in ON power state (the DSI_COMPLEXIO_CFG1[28:27] PWR_CMD bit field is set to 1) and at least one lane is enabled.

To begin transmission, the protocol drives TXREQUESTHS high on a rising edge of TXBYTECLKHS. The PHY detects this signal on the next rising edge, after which it initiates the LP SoT procedure.

During an HS clock transmission, these parameters are defined in multiples of CLKIN2DDR and are programmed by the following bit fields:

- TLPX timing is programmed by DSI_PHY_REGISTER1[20:16] TLPXBY2.
- THS-PREPARE timing is programmed by DSI_PHY_REGISTER0[31:24] THSPREPARE.
- TCLK-ZERO timing is programmed by DSI_PHY_REGISTER1[7:0] TCLKZERO.

TCLK-ZERO is extended, if required, so that the entire LP SoT procedure lasts an integer number of TXBYTECLKHS cycles.

At the end of the SoT procedure, HS clock transmission begins. At the same time, TXREADYHS is made high.

To stop clock transmission, the protocol drives TXREQUESTHS low on a rising edge of TXBYTECLKHS. The DSI_PHY_DSS_x detects this change in TXREQUESTHS on the next edge and stops clock transmission. TXREADYHS is made low.

DSI_PHY_DSS_x then goes through the LP EoT procedure. The TCLK-TRAIL and THS-EXIT parameters are also multiples of CLKIN2DDR and are programmed by the following bit fields:

- TCLK-TRAIL timing is programmed by DSI_PHY_REGISTER1[15:8] TCLKTRAIL.
- THS-EXIT timing is programmed by DSI_PHY_REGISTER0[7:0] THSEXIT.

DSI_PHY_DSS_x completes the SoT and EoT procedures, once begun, regardless of any change in the PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY starts the EoT procedure immediately after finishing the SoT procedure and no clock is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the low-power receivers. This signal is not synchronized with TXBYTECLKHS.

The HS clock must be present for a period of time before (TCLK-PRE) and after (TCLK-POST) HS data transmission. The protocol must ensure that these timings are met by asserting and deasserting TXREQUESTHS appropriately.

The PHY ensures that the clock signal has a quadrature phase with respect to a toggling bit sequence on any data lane, and a rising edge in the center of the first transmitted bit of each data byte. These relations are not described in the timing diagram.

CLKIN2DDR can be shut off 300 ns after the clock lane goes to STOPSTATE. Alternatively, CLKIN2DDR can be shut down after TCLK-Trail + THS-Exit + 2 Txbyteclk periods after the TxRequestHS falling edge is received by DSI_PHY_DSS_x.

The DSI protocol engine must ensure that TXREQUESTESC, TXULPSCLK, and TURNREQUEST are low whenever TXREQUESTHS is asserted.

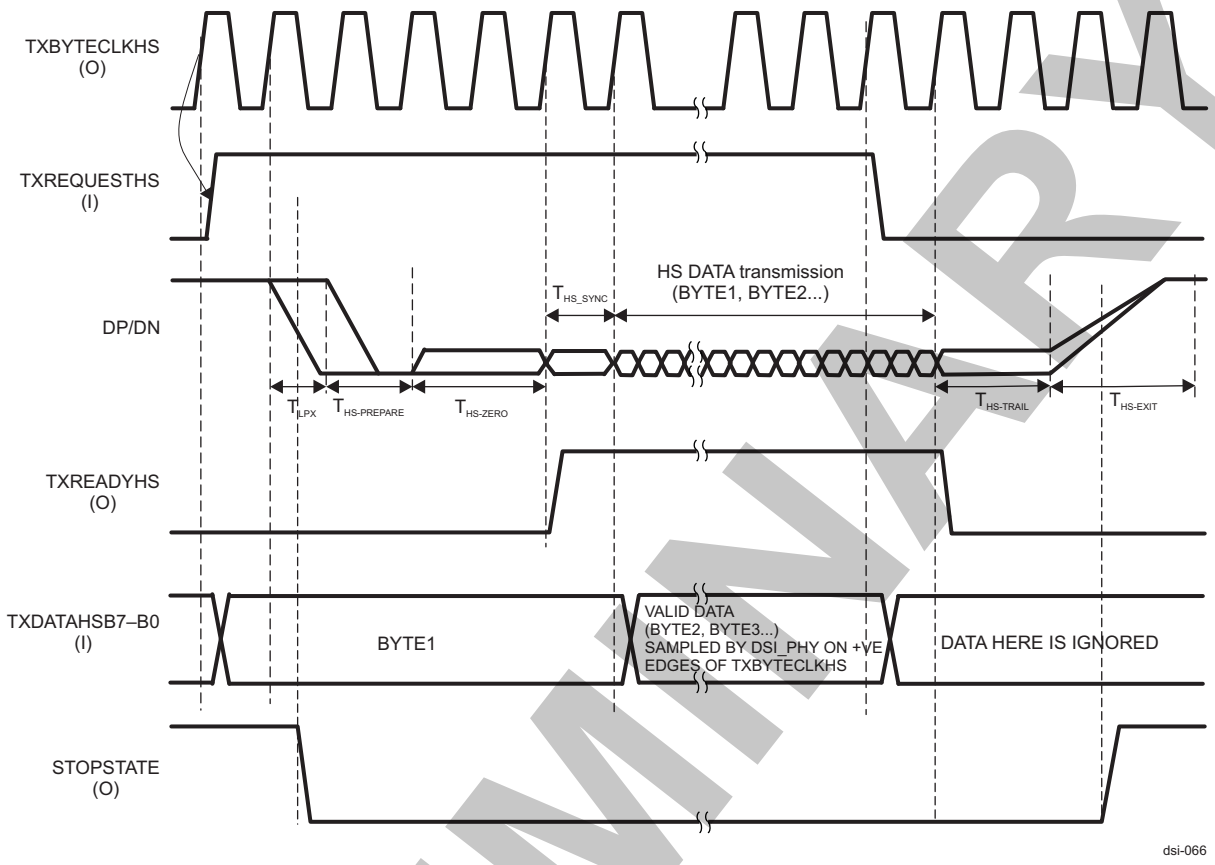
10.3.4.6.5.2 DSI PHY HS Data Transmission

Figure 10-154 shows an example of HS data transmission.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Figure 10-154. DSI PHY HS Data Transmission



To begin transmission, the protocol drives TXDATAHS with the first byte of data on a rising edge of TXBYTECLKHS. It also makes TXREQUESTHS high on the same rising edge. The PHY detects TXREQUESTHS going high on the next rising edge of TXBYTECLKHS, following which it initiates the LP SoT procedure.

During an HS data transmission, these timings are multiples of CLKIN2DDR and are programmed by the following bit fields:

- TLPX timing is programmed by DSI_PHY_REGISTER1[20:16] TLPXBY2.
- THS-PREPARE + THS-ZERO timing is programmed by DSI_PHY_REGISTER0[23:16] THSPRPR_THSZERO.

THS-ZERO is extended, if required, so that the entire LP SoT procedure lasts an integer number of TXBYTECLKHS cycles. THS-SYNC corresponds to the length of the sync pattern (8 HS bits), and can be configured through the DSI_PHY_REGISTER2[31:24] HSSYNCPATTERN bit field.

Toward the end of the SoT procedure, the PHY makes TXREADYHS high on a positive edge of TXBYTECLKHS and then starts accepting data from TXDATAHS from the next positive edge onward. The protocol is expected to provide (new) valid data on TXDATAHS on every positive edge of TXBYTECLKHS if TXREADYHS is high.

At the end of the SoT procedure, HS data transmission begins. HS data transmission happens LSB first.

To stop data transmission, the protocol drives TXREQUESTHS low on a rising edge of TXBYTECLKHS. The PHY detects this change in TXREQUESTHS on the next edge and stops data transmission. TXREADYHS is made low and data on TXDATAHS, from that point, is ignored.

The PHY then goes through the LP EoT procedure. THS-TRAIL and THS-EXIT are also multiples of CLKIN2DDR and are programmed by the following bit fields:

- THS-TRAIL timing is programmed by DSI_PHY_REGISTER0[15:8] THSTRAIL.
- THS-EXIT timing is programmed by DSI_PHY_REGISTER0[7:0] THSEXIT.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

The PHY completes the SoT and EoT procedures, once begun, regardless of any change in PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY starts the EoT procedure immediately after finishing the SoT procedure and no data is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the low-power receivers. This signal is not synchronized with TXBYTECLKHS.

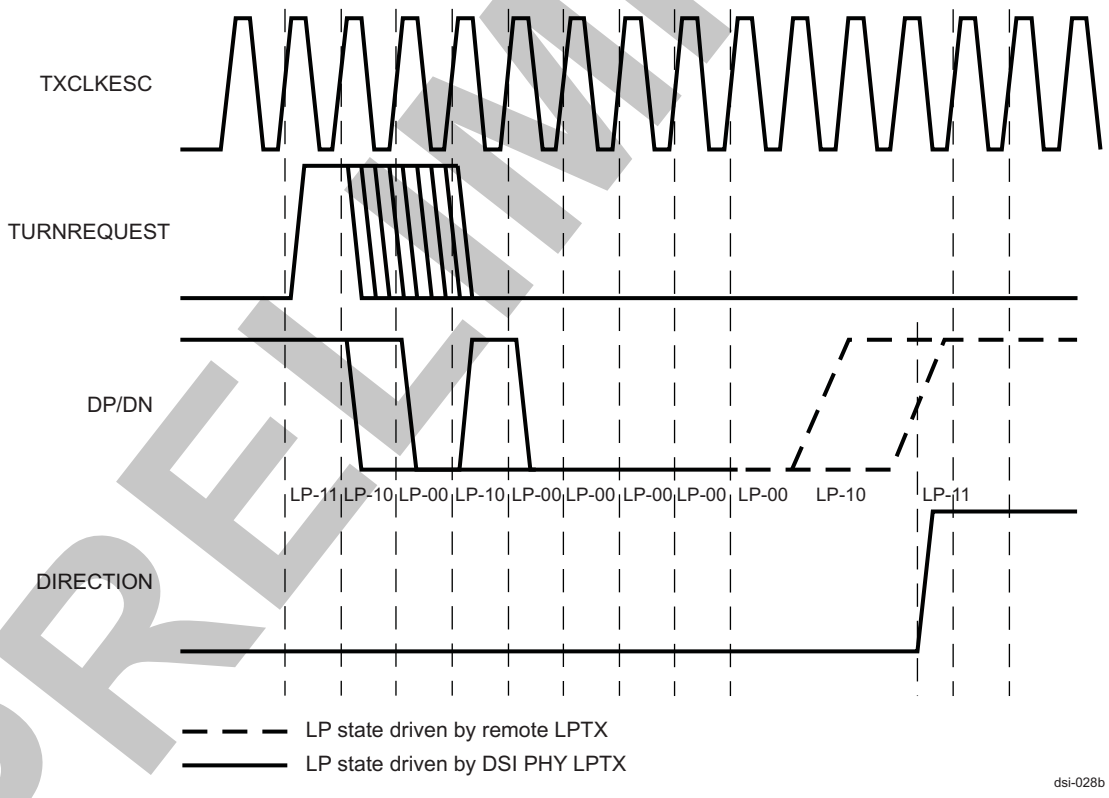
The protocol must ensure that TXREQUESTESC, TXULPSCLK, and TURNREQUEST are low whenever TXREQUESTHS is asserted.

10.3.4.6.5.3 DSI PHY Turnaround Request in Transmit Mode

When the DSI PHY is in transmit mode, the DSI protocol engine can request a turnaround by making the TurnRequest signal high for at least one clock cycle of TxClkEsc (see Section 10.3.4.4.7.3, *TurnRequest FSM*).

The DSI PHY transmits the turnaround request pattern (LP 11-10-00-10-00-00-00-00) (see Figure 10-155). The number of 00 states at the end of the pattern is defined by the T_{TA-GO} timing parameter and is programmable through the DSI_PHY_REGISTER1[31:29] REG_TTAGO bit field, in number of TxClkEsc clocks. Following the transmission of the pattern, the DSI PHY disables its LP transmitters and waits for an acknowledgment from the remote device. The remote device detects the turnaround request and acknowledges it by driving LP-10, followed by the STOP state. When this acknowledgment is received (BTA_IRQ is asserted, as described in Section 10.3.4.4.8, *DSI Bus Turnaround*), the DSI PHY switches to receive mode and indicates the completion of the turnaround procedure by changing the direction (BTA_EN = 0).

Figure 10-155. DSI PHY Turnaround Request in Transmit Mode



The DSI protocol engine must not stop TxClkEsc after the turnaround process completes (the DSI_CLK_CTRL[20] LP_CLK_ENABLE bit must be kept at 1), because TxClkEsc is also used in handling a turnaround request transmitted by a remote slave device (see Section 10.3.4.6.5.4, *Turnaround Request in Receive Mode*).

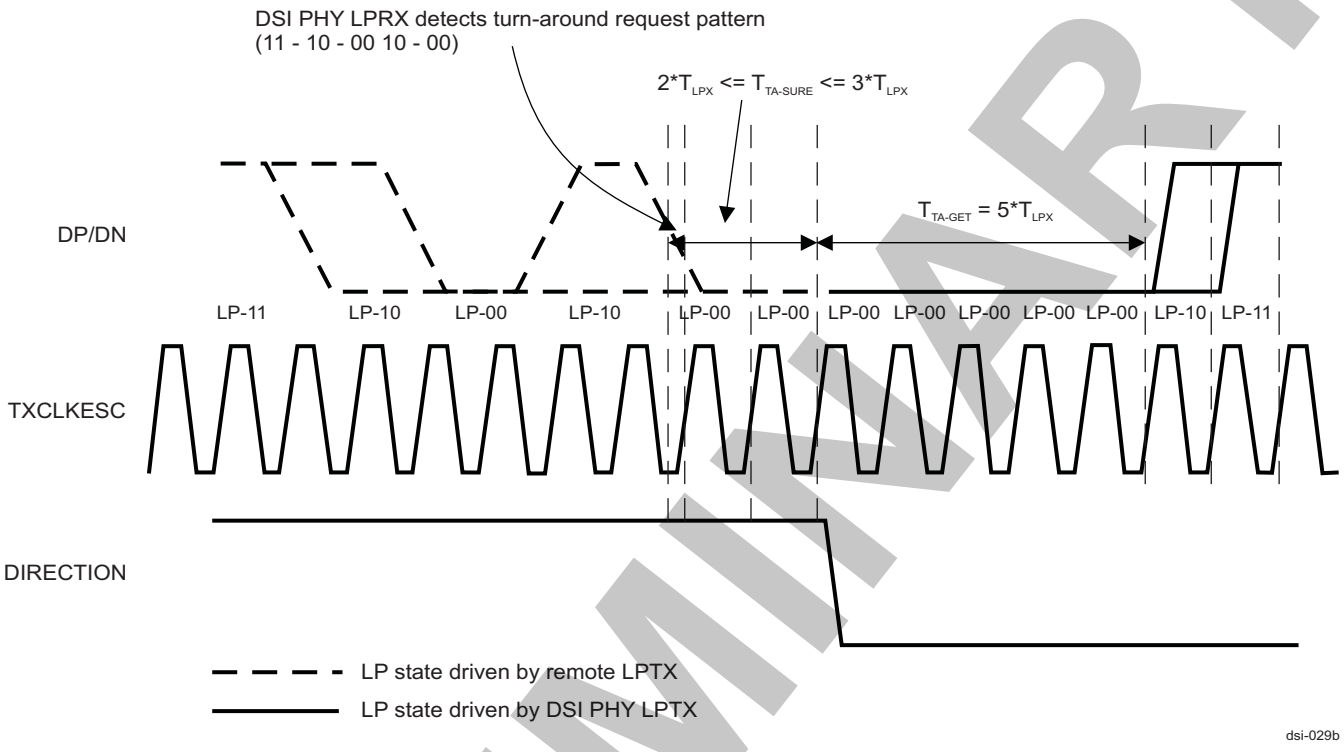
PRELIMINARY

10.3.4.6.5.4 DSI PHY Turnaround Request in Receive Mode

When DSI PHY is in receive mode, an LP pattern of 11-10-00-10-00 on DP/DN lines indicates a turnaround request from the remote device (see Figure 10-156).

Figure 10-156. DSI PHY Turnaround Request in Receive Mode



If the line stays in LP-00 for a time $T_{TA-SURE}$, the DSI PHY accepts the turnaround request, changes the direction, transmits LP-00 for a time T_{TA-GET}, and then transmits the acknowledgment pattern LP-10, followed by the STOP state.

This completes the turnaround procedure. The $T_{TA-SURE}$ and T_{TA-GET} timing parameters are programmable through DSI_PHY_REGISTER1 in number of TxClkEsc clocks:

- $T_{TA-SURE}$ can be configured in the [28:27] REG_TTASURE bit field.
- T_{TA-GET} can be configured in the [26:24] REG_TTAGET bit field.

10.3.4.6.5.5 DSI PHY Transmission and Reception

The timings of the following sequences defined in the DSI_PHY_DSS_x protocol cannot be programed by the user:

- Low-power data transmission
- Escape mode trigger command transmission
- ULPS command transmission on data lanes
- ULPS transmission on clock lane
- Low-power data in receive mode
- Low-power trigger in receive mode
- ULPS command on clock lane in receive mode
- ULPS command on data lane in receive mode

10.3.4.6.6 DSI PHY Power Management

Power management of the DSI_PHY_DSS_x analog circuitry is done through the internal power FSM, which is controlled by the subsystem. The control interface is a basic command and acknowledge protocol. The subsystem is the master of the interface. There is a dedicated command pin for each power state of DSI_PHY_DSS_x and a common acknowledge pin. The subsystem sends the power command and clock. The internal FSM does the sequencing and control generation of internal power domains. It then asserts the acknowledge, which signals the completion of the power state transition. The internal power control FSM is powered by a constant power supply.

The main features of the power control interface are:

- One dedicated command line per power state
- Only one command line can be asserted at a time.
- One acknowledge signal common to all command lines
- The command line cannot be cleared unless the acknowledge has been returned.
- All the command lines and the acknowledge signal must be cleared before triggering a new command.

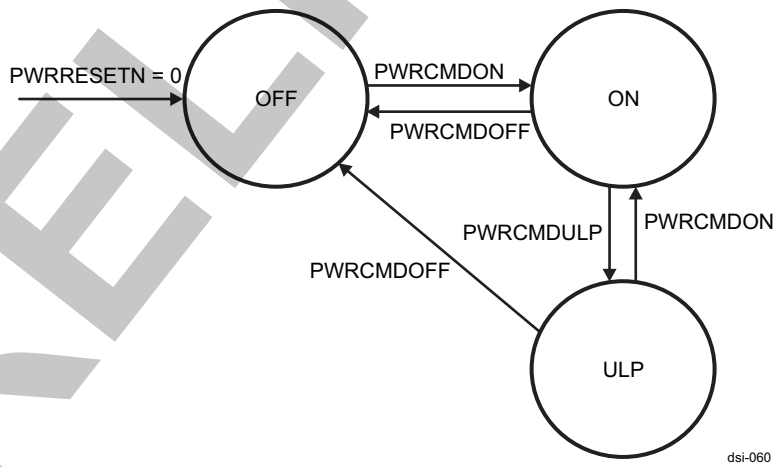
DSI_PHY_DSS_x supports three power states:

- OFF/GPIO mode (OFF): The entire analog circuit is powered down. Internal LDO is off. All analog circuitry on 1.8-V supply is powered down. The ULPS exit detection circuit power switch is off. DSI_PHY_DSS_x takes leakage level current.
- ON: Complete analog circuit is powered on and functional. LDO is on. (DSI_PHY_DSS_x calibrates every time the module enters power on state.)
- ULPS: Only the ULPS exit-detection circuit power switch in DSI_PHY_DSS_x mode is on. All the other analog circuitry is switched off. LDO is off.

NOTE: ULPS must be entered only when all used lane modules go into ULPS. The PHY power state must be returned to ON power state when any one of the used modules goes out of ULPS. No PPI signal except TXULPSEXIT must be toggled when in this power state.

Figure 10-157 shows the power states of the DSI PHY

Figure 10-157. DSI PHY Power State Diagram



10.3.4.6.6.1 DSI PHY Power Saving in DSIPHY From PLL Clock

DSIPHY can work with the 2X clock from PLL. A duty cycle corrector (DCC) is used inside DSIPHY to correct the duty cycle and allow the use of the 2X clock. Compared to legacy devices, a slower clock saves power in the PLL. Therefore, the default setting for DSIPHY is to use the 2X clock. The 2X clock is supported only from a data rate of 500 Mbps to 1,255.5 Mbps. For data rates less than 500 Mbps, the DCC must be bypassed and PLL must be programmed to the 4X clock. The DSI_PHY_DSS_x_REGISTER1 register setting for this is explained in Table 10-546.

Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

Table 10-546. DSI PHY PLL Clock Select Register Control

DSI_PHY_DSS_x_REGISTER1 Bits	Functionality	Comment
REG_DCCEN	Enable DCC.	For higher data rates, DCC must be enabled. The default value is 1 or DCC is enabled.
REG_CLKINP_SEL	Select DCC or divby2 output.	The default value is 0 or DCC output is selected.
REG_CLKPINP_DIVBY2EN	Enable divby2.	For lower data rates, 500 Mbps and below must be used.

10.3.4.6.7 DSI PHY Error Handling

A dedicated register for the DSI PHY (DSI_COMPLEXIO_IRQSTATUS) indicates the state of each error provided by the DSI PHY error signals. The DSI_PHY_DSS_x reports the following errors:

- DSI_COMPLEXIO_IRQSTATUS[9:5] ERRESCi_IRQ: ERRESC is asserted if an unrecognized Escape entry command is received. This remains high until the next change in the line state.
- DSI_COMPLEXIO_IRQSTATUS[4:0] ERRSYNCESCi_IRQ: If the number of bits received during a low-power data transmission is not a multiple of 8 when the transmission ends, ERRSYNCESC is made high and remains high until the next change in the line state.
- DSI_COMPLEXIO_IRQSTATUS[14:10] ERRCONTROLi_IRQ: ERRCONTROL is asserted if an incorrect line state sequence is detected. For example, if a turnaround request or escape mode request is immediately followed by a STOP state instead of the required bridge state, this signal is asserted and remains asserted until the next change in the line state.
- DSI_COMPLEXIO_IRQSTATUS ERRCONTENTIONLP0_i_IRQ: ERRCONTENTION0LPDX and ERRCONTENTION0LPDY are asserted when the lane module detects a contention situation on lines DX and DY, respectively, while trying to drive the lines low. Contention is detected only if it lasts at least 50 ns.
- DSI_COMPLEXIO_IRQSTATUS ERRCONTENTIONLP1_i_IRQ: ERRCONTENTION1LPDX and ERRCONTENTION1LPDY are asserted when the lane module detects a contention situation on lines DX and DY, respectively, while trying to drive the lines high. Contention is detected only if it lasts at least 50 ns.

The ULPSACTIVENOT signal goes low, which indicates to the protocol that the PHY has entered ULPS. When all the ULPSActiveNot signals are low, the DSI_COMPLEXIO_IRQSTATUS[30] ULPSACTIVENOT_ALL0_IRQ event is generated. When all the ULPSActiveNot signals are high, the DSI_COMPLEXIO_IRQSTATUS[31] ULPSACTIVENOT_ALL1_IRQ event is generated.

When any of the events defined in the DSI_COMPLEXIO_IRQSTATUS register occur, the DSI_IRQSTATUS[10] COMPLEXIO_ERR_IRQ bit is set to 1 at the DSI protocol engine level.

Table 10-547 lists the DSI PHY interrupt events.

Table 10-547. DSI PHY Interrupts

IRQ Name	Description
ULPSActiveNot_ALL0_IRQ	All ULPSActiveNOT signals are 0.
ULPSActiveNot_ALL1_IRQ	All ULPSActiveNOT signals corresponding to the lanes with TXULPSExit being high are high.
STATEULPM5_IRQ	Fifth lane n ULPS
STATEULPM4_IRQ	Fourth lane in ULPS
STATEULPM3_IRQ	Third lane in ULPS
STATEULPM2_IRQ	Second lane in ULPS
STATEULPM1_IRQ	First lane in ULPS
ERRCONTROL5_IRQ	Control error for fifth lane
ERRCONTROL4_IRQ	Control error for fourth lane
ERRCONTROL3_IRQ	Control error for third lane
ERRCONTROL2_IRQ	Control error for second lane

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 10-547. DSI PHY Interrupts (continued)

IRQ Name	Description
ERRCONTROL1_IRQ	Control error for first lane
ERRESC5_IRQ	Escape entry error for fifth lane (edge trigger interrupt)
ERRESC4_IRQ	Escape entry error for fourth lane (edge trigger interrupt)
ERRESC3_IRQ	Escape entry error for third lane (edge trigger interrupt)
ERRESC2_IRQ	Escape entry error for second lane (edge trigger interrupt)
ERRESC1_IRQ	Escape entry error for first lane (edge trigger interrupt)
ERRCONTENTIONLP1_1_IRQ	Contention LP1 error for first lane
ERRCONTENTIONLP0_1_IRQ	Contention LP0 error for first lane
ERRCONTENTIONLP1_2_IRQ	Contention LP1 error for second lane
ERRCONTENTIONLP0_2_IRQ	Contention LP0 error for second lane
ERRCONTENTIONLP1_3_IRQ	Contention LP1 error for third lane
ERRCONTENTIONLP0_3_IRQ	Contention LP0 error for third lane
ERRCONTENTIONLP1_4_IRQ	Contention LP1 error for fourth lane
ERRCONTENTIONLP0_4_IRQ	Contention LP0 error for fourth lane
ERRCONTENTIONLP1_5_IRQ	Contention LP1 error for fifth lane
ERRCONTENTIONLP0_5_IRQ	Contention LP0 error for fifth lane
ERRSYNCESC5_IRQ	Low-power data transmission synchronization error for fifth lane
ERRSYNCESC4_IRQ	Low-power data transmission synchronization error for fourth lane
ERRSYNCESC3_IRQ	Low-power data transmission synchronization error for third lane
ERRSYNCESC2_IRQ	Low-power data transmission synchronization error for second lane
ERRSYNCESC1_IRQ	Low-power data transmission synchronization error for first lane

Software must take appropriate action when receiving the interrupt indicating the error from the DSI PHY. The action can be:

- Reset the DSI protocol engine module.
- Reset the peripheral through the reset trigger or directly drive the hardware reset pin of the display module.
- Ignore the error.

10.3.5 DSI Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the DSI module.

10.3.5.1 DSI Global Initialization

10.3.5.1.1 DSI Surrounding Modules Global Initialization

This section describes the requirements to initialize the surrounding modules when the DSI module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the DSI. For more information, see Section 10.3.3, *DSI Integration*, and Section 10.3.2, *DSI Environment*.

Table 10-548 describes the global initialization of the surrounding modules.

Table 10-548. DSI Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	DSI module interface and functional clocks must be enabled. The module power management (idle and sleep modes) must be configured. For more information, see , *Module-Level Clock Management*, in *Chapter 3, Power, Reset, and Clock Management*.
MPU INTC	MPU interrupt controller (INTC) configuration must be done to enable interrupts from the DSI module. For more information about the module configuration, see , *Interrupt Controllers Overview*, in Chapter 17, *Interrupt Controllers*.
DSP INTC	DSP INTC configuration must be done to enable interrupts from the DSI module. For more information about the module configuration, see , *DSP Subsystem Overview*, in *Chapter 5, DSP Subsystem*.
DMA_SYSTEM	DMA configuration must be done to enable DSI module DMA channel requests. For more information about the configuration, see , *DMA_SYSTEM Module Overview*, in *Chapter 16, System DMA*.
L3_MAIN interconnect	For information about the interconnect configuration, see , *L3 Interconnect*, in *Chapter 14, Interconnects*.

10.3.5.1.2 DSI Global Initialization

10.3.5.1.2.1 DSI Main Sequence – DSI Global Initialization

This procedure initializes the DSI after a power on or software reset.

Table 10-549 summarizes the DSI global initialization.

Table 10-549. DSI Global Initialization

Steps	Registers	Value
Reset IRQ status.	DSI_IRQSTATUS[31:0]	0x0
Set clock activity.	DSI_SYSCONFIG[9:8] CLOCKACTIVITY	x
Configure power management.	DSI_SYSCONFIG[4:3] SIDLEMODE	x

10.3.5.2 DSI Operational Modes Configuration

10.3.5.2.1 DSI Video Mode Using the DISPC Video Port

10.3.5.2.1.1 DSI Main Sequence – DSI PLL Setup

Table 10-550 lists the steps required to configure the DSI PLL.

Table 10-550. DSI PLL Configuration Registers

Steps	Registers	Value
Turn on/off the PLL and HSDIVIDER.	DSI_CLK_CTRL[31:30] PLL_PWR_CMD	x
Wait until the status of the PLL is set (value according to the previous step)?	DSI_CLK_CTRL[29:28] PLL_PWR_STATUS	= x
Set the divider value for DSI protocol engine clock source M5REG.	DSI_PLL_CONFIGURATION1[30:26] M5_CLOCK_DIV	x
Set the divider value for clock source M4REG.	DSI_PLL_CONFIGURATION1[25:21] M4_CLOCK_DIV	x
Set the value for M divider for the PLL.	DSI_PLL_CONFIGURATION1[20:9] DSI_PLL_REGM	x
Set the value for N divider for the PLL.	DSI_PLL_CONFIGURATION1[8:1] DSI_PLL_REGN	x
Enable/disable DSI protocol engine clock divider.	DSI_PLL_CONFIGURATION2[18] M5_CLOCK_EN	x
Enable/disable M4 clock source divider.	DSI_PLL_CONFIGURATION2[16] M4_CLOCK_EN	x
Enable/disable DSI PHY clock.	DSI_PLL_CONFIGURATION2[14] PHY_CLKINEN	x
Enable/disable PLL reference clock.	DSI_PLL_CONFIGURATION2[13] PLL_REFEN	x
Set PLL automatic update mode.	DSI_PLL_CONTROL[0] PLL_AUTOMODE	x
Request PLL locking sequence.	DSI_PLL_GO[0] PLL_GO	0x1
Read until PLL_GO bit = 0?	DSI_PLL_GO[0] PLL_GO	= 0x0
Wait until PLL is locked?	DSI_PLL_STATUS[1] PLL_LOCK	= 0x1
Set the ratio for the LP clock.	DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR	x
Enable/disable DSS_L3_MAIN_ICLK clock gating to DSI_PHY_DSS_x and PLL module.	DSI_CLK_CTRL[14] CIO_CLK_ICG	x
Enable/disable the automatic assertion/deassertion of DSIStopClk.	DSI_CLK_CTRL[18] HS_AUTO_STOP_ENABLE	x
Configure the DSI functional clock synchronization and clock speed.	DSI_CLK_CTRL[21] LP_RX_SYNCHRO_ENABLE	x
Turn on/off PLL and HSDIVIDER.	DSI_CLK_CTRL[31:30] PLL_PWR_CMD	x

10.3.5.2.1.2 DSI Main Sequence – Set Up DSI Protocol Engine

10.3.5.2.1.2.1 DSI Set Up DSI Control Registers

Table 10-551 lists the steps to set up the DSI control registers. Table 10-552 lists the steps to set up the DSI PHY registers.

Table 10-551. DSI Control Registers

Steps	Registers	Value
Enable the interrupt event for lost synchronization with the video port.	DSI_IRQENABLE[18] SYNC_LOST_IRQ_EN	0x1
Enable interrupt event for sent packet on desired VC.	DSI_VC_IRQENABLE_i[2] PACKET_SENT_IRQ_EN	x
Enable HSYNC END pulse detection (short packet generation).	DSI_CTRL[17] VP_HSYNC_START	0x1
Enable VSYNC START pulse detection (short packet generation).	DSI_CTRL[15] VP_VSYNC_START	0x1
Select trigger reset mode.	DSI_CTRL[14] TRIGGER_RESET_MODE	x

Table 10-558 lists the steps to switch the DSI and DISPC module clocks to DSI PLL clock source.

Table 10-558. DSI witch to DSI PLL Clock Source

Steps	Reference	Value
Switch DISPC clock to PLL1_CLK1.	For more information, see Display Subsystem Integration, in *Display Subsystem*.	
Switch DSI clock to DPLL_DSI1_A_CLK2.	For more information, see Display Subsystem Integration, in *Display Subsystem*.	

10.3.5.2.2.3 DSI Main Sequence – Configure DSI Protocol Engine

10.3.5.2.2.3.1 DSI Set Up DSI Control Registers

Table 10-559 lists the steps required to set up the DSI control registers. Table 10-560 lists the steps to set up the DSI PHY registers.

Table 10-559. DSI Control Registers

Steps	Register/Bit Field/Programming	Value
Enable IRQ for lost synchronization with video port.	DSI_IRQENABLE[18] SYNC_LOST_IRQ_EN	0x1
Enable IRQ to indicate that packet has been sent on desired VC.	DSI_VC_IRQENABLE_i[2] PACKET_SENT_IRQ_EN	0x1
Set the trigger reset mode.	DSI_CTRL[14] TRIGGER_RESET_MODE	x
Configure the number of active line buffers.	DSI_CTRL[13:12] LINE_BUFFER	x
Set the size of the video port data bus.	DSI_CTRL[7:6] VP_DATA_BUS_WIDTH	x
Define the ratio between VP_CLK and VP_PCLK.	DSI_CTRL[4] VP_CLK_RATIO	x
Set the arbitration scheme for granting the VC pending ready requests in the TX FIFO.	DSI_CTRL[3] TX_FIFO_ARBITRATION	x
Enable/disable the ECC check for the received header.	DSI_CTRL[2] ECC_RX_EN	x

Table 10-560. DSI PHY Registers

Steps	Register/Bit Field/Programming	Value
Determine the position of the clock lane.	DSI_COMPLEXIO_CFG1[2:0] CLOCK_POSITION	x
Set the position of data lane 1.	DSI_COMPLEXIO_CFG1[6:4] DATA1_POSITION	x
Configure the power state of the DSI PHY.	DSI_COMPLEXIO_CFG1[28:27] PWR_CMD	x
Enable the synchronization of the shadow registers with DISPC_UPDATE_SYNC.	DSI_COMPLEXIO_CFG1[30] GOBIT	0x1
Clear the DSI PHY IRQ status.	DSI_COMPLEXIO_IRQSTATUS	0xFFFF FFFF
Disable all DSI PHY IRQ events.	DSI_COMPLEXIO_IRQENABLE	0x0
Enable the DSI protocol engine interface.	DSI_CTRL[0] IF_EN	0x1
Disable the DSI protocol engine interface.	DSI_CTRL[0] IF_EN	0x0
Wait until interface is disabled?	DSI_CTRL[0] IF_EN	= 0x0
Enable the LP clock.	DSI_CLK_CTRL[20] LP_CLK_ENABLE	0x1
Check whether internal reset is complete?	DSI_COMPLEXIO_CFG1[29] RESET_DONE	= 0x1
Check whether power state of DSI PHY is ON?	DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS	= 0x1
Check whether reset is complete?	DSI_SYSSTATUS[0] RESETDONE	= 0x1

10.3.5.2.2.3.2 DSI Configure DSI Timing and VCs

Table 10-561 lists the steps to configure DSI timing and the VCs.

Table 10-561. DSI Timing Registers

Steps	Register/Bit Field/Programming	Value
Determine the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[12:0] STOP_STATE_COUNTER_IO	0x-
Enable/disable the multiplication factor of 4 for the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[13] STOP_STATE_X4_IO	0x-
Enable/disable the multiplication factor of 16 for the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[14] STOP_STATE_X16_IO	0x-
Clear turnaround timer settings.	DSI_TIMING1[30:16]	0x0
Determine the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[12:0] LP_RX_TO_COUNTER	0x-
Enable/disable the multiplication factor of 4 for the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[13] LP_RX_TO_X4	0x-
Enable/disable the multiplication factor of 16 for the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[14] LP_RX_TO_X16	0x-
Determine the number of BYTE_CLK clock cycles for the HS RX timer.	DSI_TIMING2[28:16] HS_TX_TO_COUNTER	0x-
Enable/disable the multiplication factor of 16 for the number of BYTE_CLK clock cycles for the HS TX timer.	DSI_TIMING2[29] HS_TX_TO_X16	0x-
Enable/disable the multiplication factor of 64 for the number of BYTE_CLK clock cycles for the HS TX timer.	DSI_TIMING2[30] HS_TX_TO_X64	0x-
Set the number of TXBYTECLKHS clock cycles	DSI_CLK_TIMING[15:8] DDR_CLK_PRE and DSI_CLK_TIMING[7:0] DDR_CLK_POST	0x-
Configuration of VCi		
Select source of data and enable VP_STALL.	DSI_VC_CTRL_i[1] SOURCE	0x1
Enable/disable the checksum generation for the transmit payload.	DSI_VC_CTRL_i[7] CS_TX_EN	0x-
Enable/disable the ECC generation for the transmit header.	DSI_VC_CTRL_i[8] ECC_TX_EN	0x-
Enable/disable HS mode to send short and long packets to the peripheral.	DSI_VC_CTRL_i[9] MODE_SPEED	0x-
Configure DMA request for TX FIFO.	DSI_VC_CTRL_i[23:21] DMA_TX_REQ_NB	0x-
Configure DMA request for RX FIFO.	DSI_VC_CTRL_i[29:27] DMA_RX_REQ_NB	0x-
Configuration TX and RX FIFO		
Set size of the RX FIFO allocated for used VC.	DSI_RX_FIFO_VC_SIZE	0x-
Set size of the TX FIFO allocated for used VC.	DSI_TX_FIFO_VC_SIZE	0x-

10.3.5.2.2.4 DSI Main Sequence – Configure DSI_PHY_DSS_x Timing

Table 10-562 summarizes DSI_PHY_DSS_x timing settings. For more information about timing calculation, see Section 10.3.4.4.4, *DSI Clock Requirements*.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 10-562. DSI Configure DSI_PHY_DSS_x Timing

Steps	Register/Bit Field/Programming	Value
Settings of the DSI protocol timing. For a complete description of timing specifications, see Section 10.3.4.4.4, *Clock Requirements*.	DSI_PHY_REGISTER0[31:24] REG_THSPREPARE	ceil(70 ns/DDR clock period) + 2
	DSI_PHY_REGISTER0[23:16] REG_THSPRPR_THSZERO	ceil(175 ns/DDR clock period) + 2
	DSI_PHY_REGISTER0[7:0] REG_THSEXIT	ceil(145 ns/DDR clock period)
	DSI_PHY_REGISTER0[15:8] REG_THSTRAIL	ceil(60n s/DDR clock period) + 5
	DSI_PHY_REGISTER2[7:0] REG_TCLKPREPARE	ceil(65 ns/DDR clock period)
	DSI_PHY_REGISTER1[7:0] REG_TCLKZERO	ceil(265 ns/DDR clock period)
	DSI_PHY_REGISTER1[15:8] REG_TCLKTRAIL	ceil(60 ns/DDR clock period) + 2
	DSI_PHY_REGISTER1[20:16] REG_TLPXBY2	ceil(25 ns/DDR clock period)

10.3.5.2.2.5 DSI Main Sequence – Drive STOP State

Table 10-563 lists the steps to drive the STOP state.

Table 10-563. DSI Drive STOP State

Steps	Register/Bit Field/Programming	Value
Force TX stop mode.	DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO	0x1
Wait until the end of TX stop mode assertion?	DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO	= 0x1

10.3.5.2.2.6 DSI Main Sequence – Enable Command Mode Using DISPC Video Port

Table 10-564 lists the steps to enable DISPC to send frames continuously. Two BTAs must be generated:

- The first BTA gives bus possession to the display module.
- The second BTA obtains the TE trigger.

Table 10-564. DSI Enable Command Mode and Automatic TE

Steps	Register/Bit Field/Programming	Value
Insert DCS write memory continue/start code.	DSI_VC_CTRL_i[31] DCS_CMD_CODE	0x-
Enable/disable automatic insertion of DCS command codes when data is sourced by the video port.	DSI_VC_CTRL_i[30] DCS_CMD_ENABLE	0x-
Enable used VC.	DSI_VC_CTRL_i[0] VC_EN	0x1
Enable DSI protocol engine interface.	DSI_CTRL[0] IF_EN	0x1
Wait until interface is enabled?	DSI_CTRL[0] IF_EN	= 0x0
Send the sequence to receive the TE trigger from the peripheral.	DSI_VC_SHORT_PACKET_HEADER_i[31:0] HEADER	0x-
Wait until packet is sent?	DSI_VC_IRQSTATUS_i[2] PACKET_SENT_IRQ	= 0x1
Write 1 to reset the status bit.	DSI_VC_IRQSTATUS_i[2] PACKET_SENT_IRQ	0x1

NOTE: Keep reserved bits at reset value in DSI_PHY_REGISTER1 and DSI_PHY_REGISTER2.

10.3.5.2.2.7 DSI Main Sequence – Send Frame Data to LCD Panel Using Automatic TE

Table 10-565 summarizes the steps to send a frame data to the LCD panel using automatic TE.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Table 10-565. DSI Send Frame Data to LCD Panel Using Automatic TE

Steps	Register/Bit Field/Programming	Value
Enable the transfer between DISPC and DSI. Reset after the transfer is done.	For more information, see DISPC Clock Configuration, in*Display Controller*.	
Specify the number of bytes to send. When DCS insertion is used, word count (WC) must include this one DCS byte.	DSI_VC_TE_i[23:0] TE_SIZE	(WC+1)*LPP
Set up long packet header.	DSI_VC_LONG_PACKET_HEADER_i[31:0] HEADER	0x-
Enable/disable TE control.	DSI_VC_TE_i[30] TE_EN	0x1
Wait until RX FIFO is empty?	DSI_VC_CTRL_i[20] RX_FIFO_NOT_EMPTY	= 0x0
Wait until TX FIFO is not full?	DSI_VC_CTRL_i[16] TX_FIFO_FULL	= 0x0
Enable first BTA to give bus possession to the display module.	DSI_VC_CTRL_i[6] BTA_EN	0x1
Wait until BTA IRQ event occurs?	DSI_VC_IRQSTATUS_i[5] BTA_IRQ	= 0x1
Write 1 to clear BTA IRQ status bit.	DSI_VC_IRQSTATUS_i[5] BTA_IRQ	0x1
Enable the second BTA to get the TE trigger.	DSI_VC_CTRL_i[6] BTA_EN	0x1
Wait until BTA IRQ event occurs?	DSI_VC_IRQSTATUS_i[5] BTA_IRQ	= 0x1
Write 1 to clear BTA IRQ status bit.	DSI_VC_IRQSTATUS_i[5] BTA_IRQ	0x1
Wait until transfer is complete?	DSI_VC_TE_i[30] TE_EN	= 0x0

Table 10-575. DSI_IRQSTATUS

Address Offset	0x0000 0018		
Physical Address	0x5800 4018 0x5800 9018	**Instance**	DSI1_A DSI1_C
Description	Interrupt status register – All virtual channels + DSI PHY + PLL This register associates 1 bit for each virtual channel to determine which virtual channel generated the interrupt. The virtual channel must be enabled for events to be generated on that virtual channel. If the virtual channel is disabled, the interrupt is not generated.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31:25	RESERVED		R	0x00
24	DISPC_UPDATE_SYNC	Determines whether the Dispc_Update_Sync signal from the display controller is used 0x0: Dispc_Update_Sync signal is not used. 0x1: Dispc_Update_Sync signal is used.	RW	0
23	HSA_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HSA blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HSA blanking period of video mode.	RW	0
22	HBP_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HBP blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HBP blanking period of video mode.	RW	0
21	HFP_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HFP blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HFP blanking period of video mode.	RW	0

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
20	BLANKING_MODE	Blanking mode 0x0: LPS is used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE, and HFP_BLANKING_MODE, respectively) when there is no command mode data in TX FIFO ready to be sent. Thus, blanking periods can be different during the frame depending on the TX FIFO. 0x1: LONG BLANKING PACKETS are used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE, and HFP_BLANKING_MODE, respectively) regardless of the packets present in the TX FIFO ready to be sent.	RW	0
19	EOT_ENABLE	Enable EOT packets at the end of HS transmission. 0x0: No EOT packets 0x1: EOT packet is sent at all HS-to-LP transitions.	RW	0
18	VP_HSYNC_END	HSYNC end pulse 0x0: Disabled. No HSYNC END short packet is generated. 0x1: Enabled. While the HSYNC END pulse is detected, the associated short packet HSYNC END is generated.	RW	0
17	VP_HSYNC_START	HSYNC start pulse. 0x0: Disabled. No HSYNC START short packet is generated. 0x1: Enabled. While the HSYNC start pulse is detected, the associated short packet HSYNC START is generated.	RW	0
16	VP_VSYNC_END	VSYNC end pulse 0x0: Disabled. No VSYNC END short packet is generated. 0x1: Enabled. While the VSYNC END pulse is detected, the associated short packet VSYNC END is generated.	RW	0
15	VP_VSYNC_START	VSYNC start pulse 0x0: Disabled. No VSYNC START short packet is generated. 0x1: Enabled. While the VSYNC START pulse is detected, the associated short packet VSYNC START is generated.(1)	RW	0
14	TRIGGER_RESET_MODE	Selection of the trigger reset mode 0x0: Synchronized: The mode is valid only if there is virtual channel using the video mode and it is active. The principal is to wait for the current video frame to be transferred on the link. Any data received after the VSYNC are ignored. 0x1: Immediate: All pending requests in TX FIFO are taken into account for transfer scheduling, the RX FIFO is ignored, and the data from video port are ignored as soon as possible. Only the current transfer on DSI link and already scheduled ones are transmitted. All the other transfers are discarded.	RW	0
13:12	LINE_BUFFER	Number of line buffers to be used while receiving data on the video port. The valid values are from 0 to DSI_GNQ[17:16] VP1_NB_LINE_BUFFER. 0x0: No line buffer 0x1: One line buffer 0x2: Two line buffers	RW	0x0

(1) In DSI video mode, if the VSA bit field in DSI_VM_TIMING2 is set to 0x0, no vertical synchronization packet will be sent, even if VP_VSYNC_START is set to 0x1 in DSI_CTRL.

Copyright © 2013, Texas Instruments Incorporated
PRELIMINARY

Bits	Field Name	Description	Type	Reset
11	VP_VSYNC_POL	VP vertical synchronization signal polarity 0x0: VSYNC signal on the video port is active low. 0x1: VSYNC signal on the video port is active high.	RW	0
10	VP_HSYNC_POL	VP horizontal synchronization signal polarity 0x0: HSYNC signal on the video port is active low. 0x1: HSYNC signal on the video port is active high.	RW	0
9	VP_DE_POL	VP data enable signal polarity 0x0: DE signal on the video port is active low. 0x1: DE signal on the video port is active high.	RW	0
8	VP_CLK_POL	VP pixel clock polarity 0x0: The DSI protocol engine module captures the data on the VP on the pixel clock falling edge. The module connected to the VP must drive the data on the pixel clock rising edge. 0x1: The DSI protocol engine module captures the data on the VP on the pixel clock raising edge. The module connected to the VP must drive the data on the pixel clock falling edge.	RW	1
7:6	VP_DATA_BUS_WIDTH	Defines the size of the video port data bus 0x0: 16-bit data width (LSB of the 24-bit video port data bus) 0x1: 18-bit data width (LSB of the 24-bit video port data bus) 0x2: 24-bit data width (LSB of the 24-bit video port data bus)	RW	0x0
5	TRIGGER_RESET	Send the reset trigger to the peripheral. 0x0: Reads: Reset trigger generation is complete. It is reset by hardware when it completes. Writes: Cancellation of the request for reset trigger generation (may be too late because it is already ongoing) 0x1: Reads: Generation of the reset trigger has been requested by the user (may be ongoing but not yet complete). Writes: Request for reset trigger to be sent to the peripheral	RW	0
4	VP_CLK_RATIO	The field indicates the clock ratio between VP_CLK and VP_PCLK. The clock VP_PCLK is generated from VP_CLK. It is divided down. The information is used only when the video port is used to provide data in command mode. In the case of video mode, it is not used. 0x0: The clock VP_PCLK is the clock VP_CLK divided by 2. The duty cycle of VP_PCLK is 50/50. 0x1: The clock VP_PCLK is the clock VP_CLK divided by 3 or more. The duty cycle of VP_PCLK is not 50/50 for odd ratio numbers (3 , 5, 7, ...).	RW	0
3	TX_FIFO_ARBITRATION	Defines the arbitration scheme for granting the virtual channel pending ready requests in the TX FIFO 0x0: Round-robin scheme is used. 0x1: Sequential scheme is used.	RW	0
2	ECC_RX_EN	Enables the Error Correction Code check for the received header (short and long packets for all virtual channel ids). 0x0: Disabled 0x1: Enabled	RW	0

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
1	CS_RX_EN	Enables the checksum check for the received payload (long packet only for all virtual channel ids) 0x0: Disabled 0x1: Enabled	RW	0
0	IF_EN	Enables the module. When the module is disabled, the signals from the DSI PHY are gated (no updates of the interrupt status register). It is not possible to change the bit fields in the DSI_CTRL register except when IF_EN is enabled. All the other registers can be changed except those that require DSI_VC_CTRL_i[0] VC_EN to be equal to 0 to be modified. 0x0: The interface is disabled. If one of the virtual channels uses the video mode with the video port to receive data, the DSI protocol engine is disabled when the next VSYNC is received and all the data in the FIFO for the other virtual channels in command mode are sent to the peripherals (if BTA_EN is enabled, the DSI protocol must wait for the response and BTA from the peripheral before disabling all the internal logic, because an acknowledge is requested). 0x1: The interface is enabled immediately, and the data acquisition on the video port starts on the next VSYNC (video mode) or first data received in the slave port FIFO (command mode).	RW	0

Table 10-583. DSI_COMPLEXIO_CFG1

Address Offset	0x0000 0048		
Physical Address	0x5800 4048 0x5800 9048	**Instance**	DSI1_A DSI1_C
Description	Complexio configuration register for the DSI PHY. This register contains the lane configuration for the order and position of the lanes (clock and data) and the polarity order for the control of the PHY differential signals and the control bit for the power FSM.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SHADOWING	GOBIT	RESET_DONE	PWR_CMD		PWR_STATUS		RESERVED					DATA4_POL	DATA4_POSITION			DATA3_POL	DATA3_POSITION			DATA2_POL	DATA2_POSITION			DATA1_POL	DATA1_POSITION			CLOCK_POL	CLOCK_POSITION		

Bits	Field Name	Description	Type	Reset
31	SHADOWING	Shadowing configuration 0x0: Disabled. The writes to the DSI_PHY_REGISTER0 through DSI_PHY_REGISTER2 registers are done like the other SCP registers. 0x1: Enabled. The writes to the DSI_PHY_REGISTER0 through DSI_PHY_REGISTER2 registers are done only when the GOBIT is set and when the signal DISPCUpdataSync from the display controller module is active.	RW	0
30	GOBIT	Allows the synchronized update of the shadow registers when the signal DISPCUpdateSync is active. 0x0: Resets the GOBIT. The hardware has finished the update of the shadow SCP registers. The bit is reset by hardware. The software can reset the bit if the user decides to abort it. There is no guarantee that the software reset is done before the transfer of the values to the DSI PHY. 0x1: Set the GOBIT. Only when the transfer of the new values for the three first registers is completed (3, 2, 1, or 0 transfers are performed based on the number of registers to update), the GOBIT is reset. The DISPCUpdateSync signal is used to synchronize the update. The bit must be set only when it is in reset state.	RW	0
29	RESET_DONE	Internal reset monitoring of the power domain using the TXBYTECLKHS clock from the DSI PHY Read 0x0: Internal module reset is ongoing. Read 0x1: Reset completed.	R	1
28:27	PWR_CMD	Command for power control of the DSI PHY 0x0: Command to change to OFF state 0x1: Command to change to ON state 0x2: Command to change to ULTRALOW-POWER state	RW	0x0
26:25	PWR_STATUS	Status of the power control of the DSI PHY Read 0x0: DSI PHY in OFF state Read 0x1: DSI PHY in ON state Read 0x2: DSI PHY in ULTRALOW-POWER state	R	0x0
24:20	RESERVED	Reserved	R	0x0

Bits	Field Name	Description	Type	Reset
21	LP_RX_SYNCHRO_ENABLE	Defines if the functional is higher or lower than 30 MHz. The information is used to define synchronization to be used for RxValidEsc. 0x0: The DSI functional clock is equal or slower than 30 MHz. The synchronization is falling/rising. 0x1: The DSI functional clock is higher than 30 MHz. The synchronization is rising/rising.	RW	0
20	LP_CLK_ENABLE	Controls the gating of the TXCLKESC clock. 0x0: Disabled. The clock is not generated. The value of LP_CLK_DIVISOR is not used and does not need to be programmed. 0x1: Enabled. The clock is generated. The value of LP_CLK_DIVISOR is used and needs to be programmed.	RW	0
19	HS_MANUAL_STOP_CTRL	In case HS_AUTO_STOP_ENABLE=0, the bit field allows manual control of the assertion/de-assertion of the signal DSIStopClk by the user. 0x0: DSIStopClk de-assertion unconditionally. 0x1: DSIStopClk assertion unconditionally.	RW	0
18	HS_AUTO_STOP_ENABLE	Enables the automatic assertion/de-assertion of DSIStopClk signal. 0x0: Auto mode disabled. 0x1: Auto mode enabled.	RW	0
17:16	LP_CLK_NULL_PACKET_SIZE	Indicates the size of LP NULL Packets to be sent automatically when after the last LP packet transfer. It is used by the receiver to drain its internal pipeline. The valid values are from 0 to 3 bytes for the payload size.	RW	0x0
15	LP_CLK_NULL_PACKET_ENABLE	Enables the generation of NULL packet in low speed. 0x0: Disabled. The NULL packet is not sent in LP mode after the last LP packet. 0x1: Enabled. The NULL packet is sent in LP mode after the last LP packet.	RW	0
14	CIO_CLK_ICG	Gates SCPClk clock provided to DSI_PHY_DSS_x and PLL-CTRL module. 0x0: Disabled. SCPClk is not generated. It remains at 0. 0x1: Enabled. SCPClk is generated (OCP_CLK/4)	RW	0
13	DDR_CLK_ALWAYS_ON	Defines if the DDR clock is also sent when there is no HS packets sent to the peripheral (low-power mode). So TXRequest for the clock lane is not de-asserted. 0x0: Disabled. The DDR clock is only provided when HS packets are sent. 0x1: Enabled. The DDR clock is always sent to the peripheral regardless of the state of the data lanes (HS or LS mode).	RW	0
12:0	LP_CLK_DIVISOR	Defines the ratio to be used for the generation of the low-power mode clock from DSI functional clock. The supported values are from 1 to 8191(the value 0 is invalid). The output frequency shall be in the range between 20 MHz and 32 kHz.	RW	0x0001

Bits	Field Name	Description	Type	Reset
9	LANE5_ULPS_SIG2	Enables the ULPS for the lane 5. The hardware shall change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxRequestEsc is changed if lane 5 is a data lane. The state of the signal TxUlpsClk is changed if lane 5 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective. WRITE: Request to change to inactive state 0x1: READ: Active state effective. WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc.	RW	0
8	LANE4_ULPS_SIG2	Enables the ULPS for the lane 4. The hardware shall change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxRequestEsc is changed if lane 4 is a data lane. The state of the signal TxUlpsClk is changed if lane 4 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective. WRITE: Request to change to inactive state 0x1: READ: Active state effective. WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc.	RW	0
7	LANE3_ULPS_SIG2	Enables the ULPS for the lane 3. The hardware shall change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxRequestEsc is changed if lane 3 is a data lane. The state of the signal TxUlpsClk is changed if lane 3 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective. WRITE: Request to change to inactive state 0x1: READ: Active state effective. WRITE: Change request to active. Bits	Field Name	Description	Type	Reset
16	TX_FIFO_FULL	FIFO status in command mode. Otherwise, this bit can be ignored. Read 0x0: The TX FIFO is not full (the FIFO can accept at least one more 32-bit value) Read 0x1: The TX FIFO is full	R	0
15	VC_BUSY	Indicates if previously scheduled activities (packets, BTA) are still being processed. Forced to 1 if VC is enabled. Software should check this bit is 0 before changing channel configuration. Read 0x0: No pending operations for this VC Read 0x1: Pending operations for this VC	R	0
14	PP_BUSY	Ping-pong buffer busy status. Read 0x0: Software is permitted to write a new header for VP command mode traffic. Read 0x1: Software is NOT permitted to write a new header for VP command mode traffic.	R	0
13	VP_SOURCE	Selection between video port 1 and video port 2. If DSI_GNQ[24] NB_VIDEO_PORTS = 0, the bit field is ignored since only video port 1 is present. 0x0: The video port 1 is selected. 0x1: The video port 2 is selected.	RW	0
12	RGB565_ORDER	Byte order for RBG565 0x0: Byte order as for DBI compliance 0x1: Byte order as for video mode	RW	0
11:10	OCP_DATA_BUS_WIDTH	Defines the size of the Interface data bus 0x0: 16-bits data width (LSB of the 32-bit Interface port data bus) 0x1: 24-bits data width (LSB of the 32-bit Interface port data bus) 0x2: 2x16-bits data width (first pixel on the LSB of the 32-bit Interface port data bus and second pixel on the MSB of the 32-bit Interface port data bus for the same Interface access) 0x3: 32-bits data width	RW	0x0
9	MODE_SPEED	Selection of the mode. The information is used by hardware only if MODE=COMMAND_MODE otherwise it is ignored. 0x0: Low-power mode (CMOS) is used to send short and long packets to the peripheral. 0x1: High Speed mode (SLVS) is used to send short and long packets to the peripheral.	RW	0
8	ECC_TX_EN	Enables the Error Correction Code generation for the transmit header (short and long packets). 0x0: Disabled 0x1: Enabled	RW	0
7	CS_TX_EN	Enables the checksum generation for the transmit payload (long packet only). 0x0: Disabled. The value 0x00 is used. 0x1: Enabled. The checksum value is calculated by HW.	RW	0

PRELIMINARY

Bits	Field Name	Description	Type	Reset
6	BTA_EN	Send the bus turn around to the peripheral. It can be used when the automatic mode is enabled (BTA_SHORT_EN=1 or/and BTA_LONG_EN=1). In that case only one BTA is sent to the peripheral. The manual mode is used to allow the user to define for which packets, the turn around is required for example getting acknowledge from the peripheral. 0x0: Reads: BTA generation is completed. It is reset by hardware when it is completed. Writes: Cancellation of the BTA generation (not guarantee since it could already on going, shall not be used). 0x1: Reads: BTA generation has been requested by user (it could be on going but not completed). Writes: Request for BTA generation.	RW	0
5	TX_FIFO_NOT_EMPTY	FIFO status Read 0x0: The TX FIFO is empty (the FIFO does not contain any data for the virtual channel) Read 0x1: The TX FIFO is not empty (the FIFO contains at least one byte for the virtual channel)	R	0
4	MODE	Selection of the mode 0x0: Command mode. 0x1: Video mode. The bit fields MODE_SPEED and SOURCE are not used by hardware. The bit field VP_SOURCE is used to select between video port 1 and video port 2 when two video ports are present.	RW	0
3	BTA_LONG_EN	Enables the automatic bus turn-around after completion of each long packet transmission. 0x0: Disabled 0x1: Enabled	RW	0
2	BTA_SHORT_EN	Enables the automatic bus turn-around after completion of each short packet transmission. 0x0: Disabled 0x1: Enabled	RW	0
1	SOURCE	Selection of the source between Interface and the Video port(s) (used by the hardware only if MODE=COMMAND MODE (0x0) otherwise it is ignored). The number of available video ports is defined in DSI_GNQ[24] NB_VIDEO_PORTS bit. 0x0: All the data are provided by the slave port. Any transfer on the video port is ignored for this virtual channel. 0x1: If MODE=VIDEO_MODE. the data received on the video port 1 or video port 2, selected using VP_SOURCE (pixels and enabled synchronization events using DSI_CTRL[17] VP_HSYNC_START, DSI_CTRL[18] VP_HSYNC_END, DSI_CTRL[15] VP_VSYNC_START, DSI_CTRL[16] VP_VSYNC_END for video port 1 and DSI_CTRL2[] VP_HSYNC_START, DSI_CTRL2[] VP_HSYNC_END, DSI_CTRL2[] VP_VSYNC_START, DSI_CTRL2[] VP_VSYNC_END for video port 2) are sent on the virtual channel (only one virtual channel can be associated with the video port, it is the software responsibility to ensure that no more than one virtual channel is enabled with the video port as the main source for data). If MODE=COMMAND_MODE, the VP.STALL signal is used by the protocol engine to indicate when new data are required. The synchronization signals are not generated by the display controller. Regardless of the MODE, no data can be provided on the Interface slave port.	RW	0

Description	CONTROL REGISTER - Virtual channel This register controls the tearing effect logic. It defines the size of the transfer when TE occurs and enables the automatic TE mode.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TE_START	TE_EN	TE_LINE	TE_LINE_NB	RESERVED				TE_SIZE																							

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
31	TE_START	Manual control of the start of the transfer. The user can use the TE interrupt in order to know that the TE trigger has been received prior to set the TE_START bit field. It is not mandatory to use the TE interrupt. 0x0: Indicates the end of the transfer. The bit can be used by user to cancel the transfer if not already started. The FIFO shall be flushed by software to ensure there is no data remaining in it. 0x1: Starts the transfer of the data. The size is defined in TE_SIZE. The bit field is set until the transfer is completed. It is reset by hardware when the transfer is completed.	RW	0
30	TE_EN	Tearing Effect Control 0x0: Disables the automatic transfer. The user shall use the interruption in order to know when TE PHY trigger is received or when the TE is detected on the input CMOS signals. The hardware reset the bit field when the transfer is completed (TE_SIZE=0). 0x1: Enables the automatic transfer of the data using the TE PHY trigger or one of the TE input signals as a synchronization event. The bit field TE_LINE defines if the CMOS signal is used or if the PHY trigger is used.	RW	0
29	TE_LINE	0x0: Disabled the TE CMOS signaling for the automatic data transfer. The DSI PHY trigger is used for the automatic data transfer. 0x1: Enables the TE CMOS signaling for the automatic data transfer. The DSI PHY trigger is not used for the automatic data transfer.	RW	0
28	TE_LINE_NB	Selection between TE0 and TE1 CMOS signals. 0x0: TE0 CMOS input line is selected 0x1: TE1 CMOS input line is selected	RW	0
27:24	RESERVED		R	0x0
23:0	TE_SIZE	Defines the number of byte (payload data excluding the check -sum) to be sent. The write into the register DSI_VC_LONG_PACKET_HEADER_i shall be performed by the user before sending data from the register DSI_VC_LONG_PACKET_PAYLOAD_i. The register value is decremented for every byte sent of the DSI link. At the end of the transfer (TE_SIZE=0), the bit field TE_EN is reset by hardware. The DMA request will be asserted when the trigger is received in order to receive data in the TX FIFO. It should not be deasserted until all data (TE_SIZE) have been received in the FIFO.	RW	0x000000

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		R	0x000000
8	PP_BUSY_CHANGE_IRQ_EN	Video port ping-pong buffer busy status 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0
7	FIFO_TX_UDF_IRQ_EN	FIFO underflow enable. The FIFO used for buffering the data received on the L3_MAIN interface slave port for the virtual channel has underflowed which means that the data for the current packet have not been received in time since the transfer of the packet are already started (transfer started since the packet size is bigger than space allocated in the FIFO). 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0
6	ECC_NO_CORRECTION_IRQ_EN	ECC error (short and long packets). No correction of the header because of more than 1-bit error. 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0
5	BTA_IRQ_EN	Virtual channel -Bus turn around reception 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0
4	FIFO_RX_OVF_IRQ_EN	FIFO overflow enable. The FIFO used on the L3_MAIN interconnect slave port for buffering the data received on the DSI link for the virtual channel has overflowed. 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0
3	FIFO_TX_OVF_IRQ_EN	FIFO overflow enable. The FIFO used on the L3_MAIN interconnect slave port for buffering the data received on the Interface slave port for the virtual channel has overflowed. 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0
2	PACKET_SENT_IRQ_EN	Indicates that a packet has been sent. It is used when BTA manual mode is used. 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0
1	ECC_CORRECTION_IRQ_EN	Virtual channel - ECC has been used to correct the only 1-bit error (short and long packet). 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0
0	CS_IRQ_EN	Virtual channel - checksum of the payload mismatch detection 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0

PRELIMINARY

Bits	Field Name	Description	Type	Reset
31:24	REG_THSPREPARE	REG_THSPREPARE timing parameter in multiples of DDR clock period. DDR clock = CLKIN2DDR/2. D-PHY specification: 40 ns + 4 * UI ÷ 85 ns + 6 * UI. UI = Unit Interval, equal to the duration of any HS state on the clock lane. Default value is programmed for 400 MHz.	RW	0x1E
23:16	REG_THSPRPR_THSZERO	REG_THSPREPARE_THSZERO timing parameter in multiples of DDR clock period. DDR clock = CLKIN2DDR/2. D-PHY specification: > 145 ns + 10 * UI. Default value is programmed for 400 MHz.	RW	0x48
15:8	REG_THSTRAIL	REG_THSTRAIL timing parameter in multiples of DDR clock period. DDR clock = CLKIN2DDR/2. D-PHY specification: > 60 ns + 4 * UI. Default value is programmed for 400 MHz.	RW	0x1D
7:0	REG_THSEXIT	REG_THSEXIT timing parameter in multiples of DDR clock frequency. DDR clock = CLKIN2DDR/2. D-PHY specification: > 100 ns. Default value is programmed for 400 MHz.	RW	0x3A

Description	Configuration register for LP mode and HS mode timings		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REG_TTAGO			REG_TTASURE			REG_TTAGET		REG_CLKINP_SEL	REG_CLKPINP_DIVBY2EN	REG_DCCEN	REG_TLPXBY2					REG_TCLKTRAIL								REG_TCLKZERO							

Bits	Field Name	Description	Type	Reset
31:29	REG_TTAGO	TTA-GO timing in terms of number of TXCLKESC clocks. 0x0: 2 cycles 0x1: 3 cycles 0x2: 4 cycles	RW	0x2

Copyright © 2013, Texas Instruments Incorporated
PRELIMINARY

Bits	Field Name	Description	Type	Reset
		0x3: 5 cycles		
		0x4: 6 cycles		
		0x5: 7 cycles		
		0x6: 8 cycles		
		0x7: 9 cycles		
		Default value: 4 cycles		
28:27	REG_TTASURE	TTA-SURE timing in terms of number of TXCLKESC clocks.	RW	0x0
		0x0: 2 cycles		
		0x1: 1 cycles		
		0x2: 3 cycles		
		0x3: 4 cycles		
		Default value: 2 cycles		
26:24	REG_TTAGET	TTA-GET timing in terms of number of TXCLKESC clocks.	RW	0x2
		0x0: 3 cycles		
		0x1: 4 cycles		
		0x2: 5 cycles		
		0x3: 6 cycles		
		0x4: 7 cycles		
		0x5: 8 cycles		
		0x6: 9 cycles		
		0x7: 10 cycles		
		Default value: 5 cycles		
23	REG_CLKINP_SEL	0x0: Default Selects DCC Output	RW	0x0
		0x1: Selects Divby2 Output		
22	REG_CLKPINP_DIVBY2EN	0x0: Default	RW	0x0
		0x1: Enables DivBy2 in Clock Input Path		
21	REG_DCCEN	0x0: Default Enables Duty Cycle Corrector	RW	0x1
		0x1: Disable the DCC clock path		
20:16	REG_TLPXBY2	(TLPX)/2 timing parameter in multiples of DDR clock frequency. DDR clock = CLKIN2DDR/2.	RW	0x0A
		Default value is programmed for 400 MHz. This is the internal timer value. The value seen on line will have variance due to rise/fall mismatch effects.		
		Note: TLPX is used to define the length of LP-01 state in HS start of Transmission sequences on clock and data lanes. For all other purposes TLPX is defined by the period of TXLPESC		
15:8	REG_TCLKTRAIL	REG_TCLKTRAIL timing parameter in multiples of DDR clock frequency. DDR clock = CLKIN2DDR/2.	RW	0x1A
		D-PHY specification: > 60 ns.		
		Default value is programmed for 400 MHz		
7:0	REG_TCLKZERO	REG_TCLKZERO timing parameter in multiples of DDR clock period. DDR clock = CLKIN2DDR/2.	RW	0x6A
		D-PHY specification: (REG_TCLKPREPARE + REG_TCLKZERO) > 300 ns.		
		Derived specification for REG_TCLKZERO (Min REG_TCLKPREPARE = 38 ns): REG_TCLKZERO > 262 ns.		
		Default value is programmed for 400 MHz

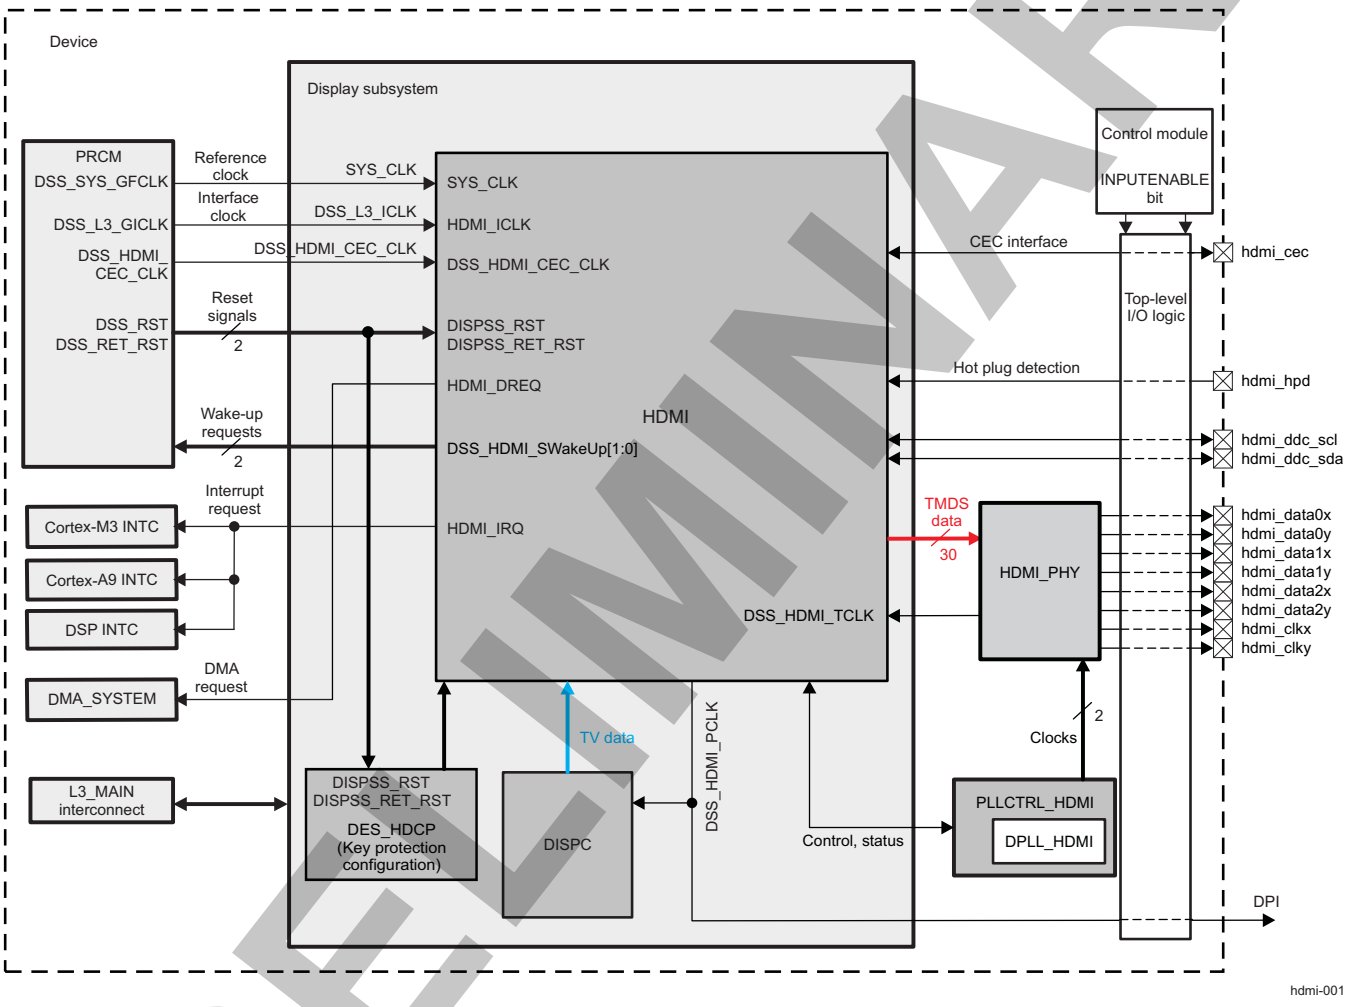
10.4 High-Definition Multimedia Interface

This section introduces the high-definition multimedia interface (HDMI) module and describes its main functions and connections in the device.

10.4.1 HDMI Overview

Figure 10-158 shows an overview of the HDMI module.

Figure 10-158. HDMI Overview



10.4.1.1 HDMI Main Features

The HDMI module provides the following main features:

- HDMI 1.4, HDCP 1.4, and DVI 1.0 compliant
  - Includes support for the 3D stereoscopic frame-packing formats of the HDMI v1.4 standard (1080p24Hz, 720p50Hz, 720p60Hz + side-by-side half structure: 1080p60Hz)
- EIA/CEA-861-D video format support (See Table 10-679 for more information.)
- VESA DMT video format support (See Table 10-680 for more information.)
- Support for deep-color mode:
  - 12-bit and 10 bit per color component deep-color modes up to 1080p @60Hz
- Supports up to 148.5-MHz pixel clock (1920 x 1080p @60Hz)
- Video formats:

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- ❑ 24/30/36-bit RGB/YCbCr 4:4:4 (deep color)
- ❑ 16/20/24-bit YCbCr 4:2:2

- Uncompressed multichannel (up to 8 channels) audio (L-PCM) support
- Master I2C interface for display data channel (DDC) connection
- Consumer electronic control (CEC) interface
- Integrated high-bandwidth digital content protection (DES_HDCP) encryption engine to transmit protected audio and video content (authentication performed by software)
- Integrated transition minimized differential signaling (TMDS) and TMDS error reduction coding (TERC4) encoders for data island support
- Integrated TMDS PHY (3 TMDS differential data lanes + TMDS differential clock lane)
  - Up to 2.97 Gbps per lane at (1080p @60Hz at 10 bits/component and 12 bits/component)

10.4.1.2 HDMI Video Formats and Timings

10.4.1.2.1 HDMI CEA-861-D Video Formats and Timings

Table 10-679 presents the video timings supported by the HDMI module, according to the CEA-861-D standard:

10.5 Remote Frame Buffer Interface

This section describes the remote frame buffer interface (RFBI).

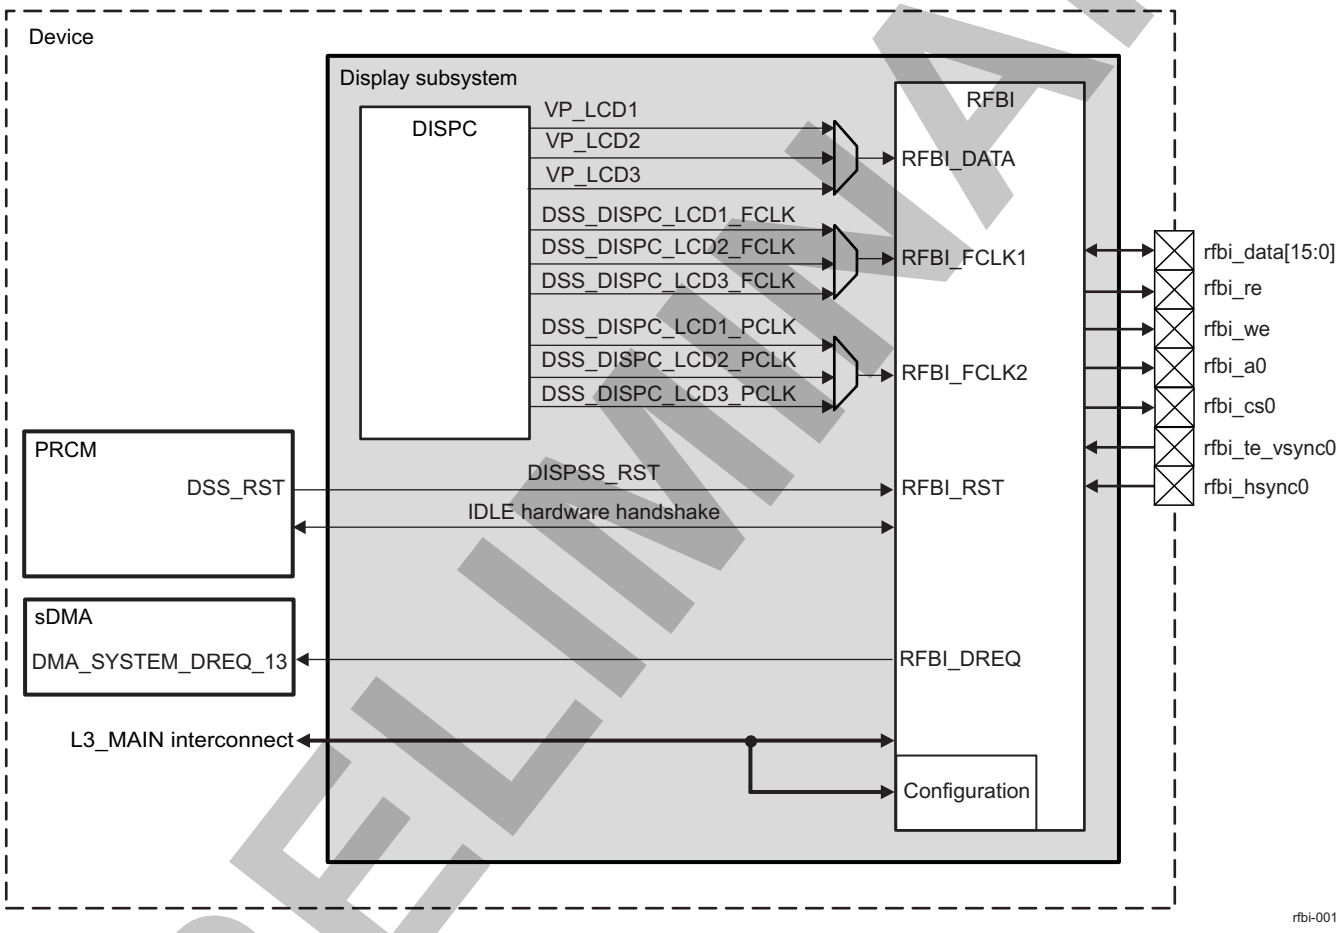
10.5.1 RFBI Overview

The RFBI module is part of the display subsystem that provides the logic to display a picture from the memory frame buffer (SDRAM or SRAM) on an LCD panel.

The RFBI is connected to the L3_MAIN interconnect through the display subsystem local interconnect.

Figure 10-159 shows an overview of the RFBI.

Figure 10-159. RFBI Highlight



The RFBI supports the MIPI DBI protocol with the following features:

- Access to RFB direct MPU interface
  - Sends commands to the RFB panel through the slave port interconnect
  - Sends data, received from the DISPC or from the MPU through the DISPC pixel data bus, to the RFB panel
  - Reads data/status from the RFB to the slave port interconnect
- RFB interface
  - 8-/9-/12-/16-bit parallel interface
  - Three programmable configuration (LCD1, 2, and 3) for an LCD connected to the RFBI
- Data formats
  - Programmable pixel modes (12-/16-/18-/24-bpp modes in RGB format)
  - Programmable output formats on one/multiple cycles per pixel (data from the DISPC and the

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

L3_MAIN interconnect)

- FIFO
  - One slave port with DMA request and interconnect FIFO of 24 × 32-bit depth (for write access to the RFBI_DATA register only)
  - One video port FIFO of 8 × 24-bit depth receiving data from the DISPC through RFBI_DATA

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

10.5.2 RFBI Environment

In the display subsystem, data are read by the DISPC from the memory frame buffer (SDRAM, SRAM, IVA-HD SL2, etc.), and sent through the RFBI to the external LCD/RFB.

The DISPC associated with the RFBI implements the MIPI DBI protocol.

The DISPC provides the required control signals to interface the memory frame buffer (SDRAM, SRAM or IVAHD-SL2) directly to the external displays. The RFBI is connected to the memory through the L3_MAIN interconnect and has its own DMA (with embedded FIFOs) to read data from the system memory. There is one master port (L3_MAIN interconnect) and one slave port.

The DISPC_CONTROL1[16] GPOUT[1] and DISPC_CONTROL1[15] GPOUT[0] bits control selection of the display subsystem modules (see Table 10-681).

Table 10-681. RFBI I/O Pad Mode Selection

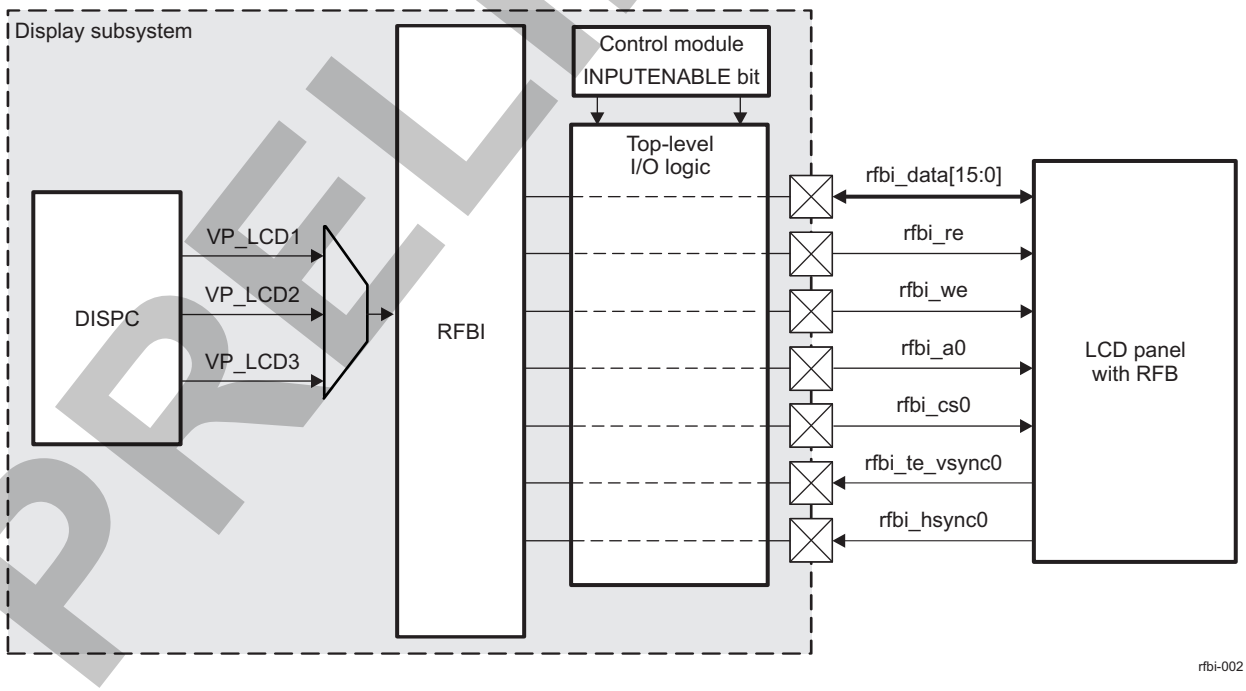
DSS.DISPC_CONTROL[16] GPOUT1	DSS.DISPC_CONTROL[15] GPOUT0	Mode
0	0	Reset
0	1	RFBI mode
1	0	Invalid
1	1	Bypass mode

The RFB of the LCD panel is directly connected to the RFBI of the device. The RFBI controls the reads/writes from/to the RFB. The RFBI receives data from its slave port or output from the DISPC and generates the signals to control the LCD panel. Through the RFBI, the MPU can send commands or parameter/display data to the LCD panel and directly set the DISPC registers to read/write data from/to the memory in the LCD panel. The RFBI can manage only one LCD panel at a time, although a sequential configuration is also possible.

10.5.2.1 RFBI Parallel Interface (MIPI DBI Protocol)

Figure 10-160 shows the LCD support parallel interface in RFBI mode.

Figure 10-160. RFBI LCD Support Interface



PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the control module registers and dedicated IP registers. For more information, see , *Pad Functional Multiplexing and Configuration*, and , *Device Interfaces Signal Group Controls Mapping*, in Chapter 18, *Control Module*.

Table 10-682 describes the interface signals to/from the LCD panel.

Table 10-682. RFBI LCD Interface Signals

Signal Name	Type[1]	Description
rfbi_data[15:0]	I/O	RFBI I/O data
rfbi_re	O	Read access signal
rfbi_we	O	Write access signal
rfbi_a0	O	Command/data selection signal
rfbi_cs0	O	Chip-select (CS) signal for LCD
rfbi_te_vsync0	I	Tearing effect (TE) synchronization signal (TE or VSYNC for LCD panel 1)
rfbi_hsync0	I	HSYNC from LCD panel

(1) I = Input; O = Output; I/O = Input/Output

- rfbi_data[15:0]: The pixel data comprises the RFBI pixel data (bits 15:0). A write/read command must be sent to the LCD panel to send/read the data.

  Before any data access, the application must send commands and parameters when it is necessary to configure an LCD panel. The data is used as input in read operations during production test and also to read the status of the registers in the LCD panel and pixels from the embedded frame buffer in the LCD panel.
- rfbi_re: The read-enable signal indicates an ongoing read from the embedded memory in the LCD panel. The RFBI registers describe the behavior of the read signal (off/on/cycle time). The polarity of the read-enable signal is programmable. The read is used to obtain status/data information from the LCD panel.
- rfbi_we: The write-enable signal indicates an ongoing write. The RFBI registers allow flexible behavior of the write signal (programmable off/on/cycle times and signal polarity).
- rfbi_a0: The signal is asserted to indicate its status: Command or data. The polarity is programmable and the status of the signal depends on the RFBI registers written by the application (CMD/READ/STATUS/PARAM/PIXEL). The register in use by the hardware defines the status of rfbi_a0. The order of the writes/reads to the RFBI registers CMD/READ/STATUS/PARAM/PIXEL defines the transitions of A0.
- rfbi_cs0: The signal is the chip-select (CS0) asserted to indicate which LCD panel is selected and must be ready to receive/transmit commands and data. When RE or WE is on, CS0 must not be changed.

  To select the trigger mode, configure the RFBI_CONFIG[3:2] TRIGGERMODE bit field (0x0: Internal trigger mode with the RFBI_CONTROL[4] ITE bit; 0x1: External trigger mode with the TE signal rfbi_tevsync0; 0x2: External trigger mode with the rfbi_tevsync0 and rfbi_hsync0 signals with the programmable line counter).
- rfbi_te_vsync0 (used by RFBI only if RFBI_CONFIG[3:2] TRIGGERMODE = 0x1 or 0x2; otherwise, this signal is ignored): Based on the trigger mode selected, the signal is the TE pulse signal or the LCD panel vertical synchronization (VSYNC) pulse signal. TE logic uses rfbi_te_vsync0 as the synchronization signal to send the pixel to the LCD panel.
- rfbi_hsync0 (used by RFBI only if RFBI_CONFIG[3:2] TRIGGERMODE = 0x2, otherwise, this signal is ignored): The HSYNC pulse signals indicate to the RFBI when horizontal synchronization occurs. The polarity of the HSYNC signals is programmable. The minimum pulse width of the signal is two RFBI_ICLK clock cycles. TE logic uses rfbi_hsync0 as a synchronization signal to send the pixel to the LCD panel.

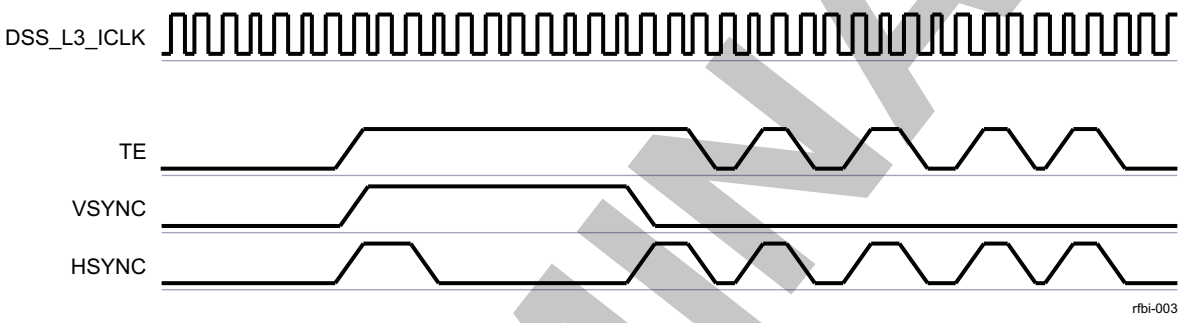
10.5.2.1.1 RFBI Description of the Tearing Effect Pulse Signal

The TE signal can be generated externally by the RFBI depending on the value of the RFBI_CONFIG[3:2] TRIGGERMODE bit field:

- TRIGGERMODE = 0x1: External trigger mode with the TE signal, which corresponds to the rfbi_te_vsync0 pad.
- TRIGGERMODE = 0x2: External trigger mode with the HSYNC/VSYNC signals. The HSYNC signal corresponds to the rfbi_hsync0 pad. The VSYNC signal corresponds to the rfbi_te_vsync0 pad.

The externally generated TE synchronization signal is a logical OR or AND operation between the HSYNC and VSYNC signals (see Figure 10-161). The logical operation (OR or AND) depends on the polarity of the HSYNC and VSYNC signals. The VSYNC signal indicates to the RFBI when vertical synchronization occurs. The HSYNC signal indicates to the RFBI when horizontal synchronization occurs.

Figure 10-161. RFBI External Generation of TE Signal Based on Logical OR Operation Between HSYNC and VSYNC (Active High)



- The TE signal is connected to the rfbi_te_vsync0 external pad when the RFBI_CONFIG[3:2] TRIGGERMODE bit field is set to 0x1.
- The HSYNC and VSYNC signals are connected to rfbi_hsync0 and rfbi_te_vsync0, respectively, when the RFBI_CONFIG[3:2] TRIGGERMODE bit field is set to 0x2.

The RFBI module detects the VSYNC and HSYNC pulses embedded in the received signal. VSYNC is detected based on the minimum pulse width defined by the RFBI_VSYNC_WIDTH register. VSYNC is not triggered by an inactive-to-active edge.

HSYNC is detected based on the minimum pulse width defined by the RFBI_HSYNC_WIDTH register. HSYNC is not triggered by an inactive-to-active edge.

The signal is generated from external logic based on VSYNC and HSYNC of the LCD panel. The automatic trigger can be programmed based on the external RFBI_TE signal or use the RFBI_CONTROL[4] ITE bit to start data capture (internal trigger mode).

The polarity of the TE signal is programmable in the RFBI_CONFIG register. HSYNC and VSYNC pulses embedded in the TE signal have the same polarity, which is active high for an ORed signal and active low for an ANDed signal. The minimum pulse width of the signal is two RFBI_ICLK clock cycles. Hardware resets the line counter when VSYNC occurs and increments it at every HSYNC. Transfer to the LCD panel begins when the line counter reaches the programmable line number.

10.5.2.2 RFBI Transaction Timing Diagrams

Table 10-683 lists the programmable timing fields. Figure 10-162 through Figure 10-164 show timing diagrams of read/write transactions to the LCD panel for the RFBI. In these figures, the polarity 0 (active low) describes the RFBI_A0, RFBI_CSi, RFBI_RE, and RFBI_WE signals.

Table 10-683. RFBI Programmable Timing Fields in RFBI Mode

Timing Name	Register Field	Description
CSOnTime	RFBI_ONOFF_TIME[3:0] CSONTIME bit field	CS assertion time from start access time
CSOffTime	RFBI_ONOFF_TIME[9:4] CSOFFTIME bit field	CS deassertion time from start access time

10.5.4 RFBI Functional Description

This section describes the functions of the RFBI.

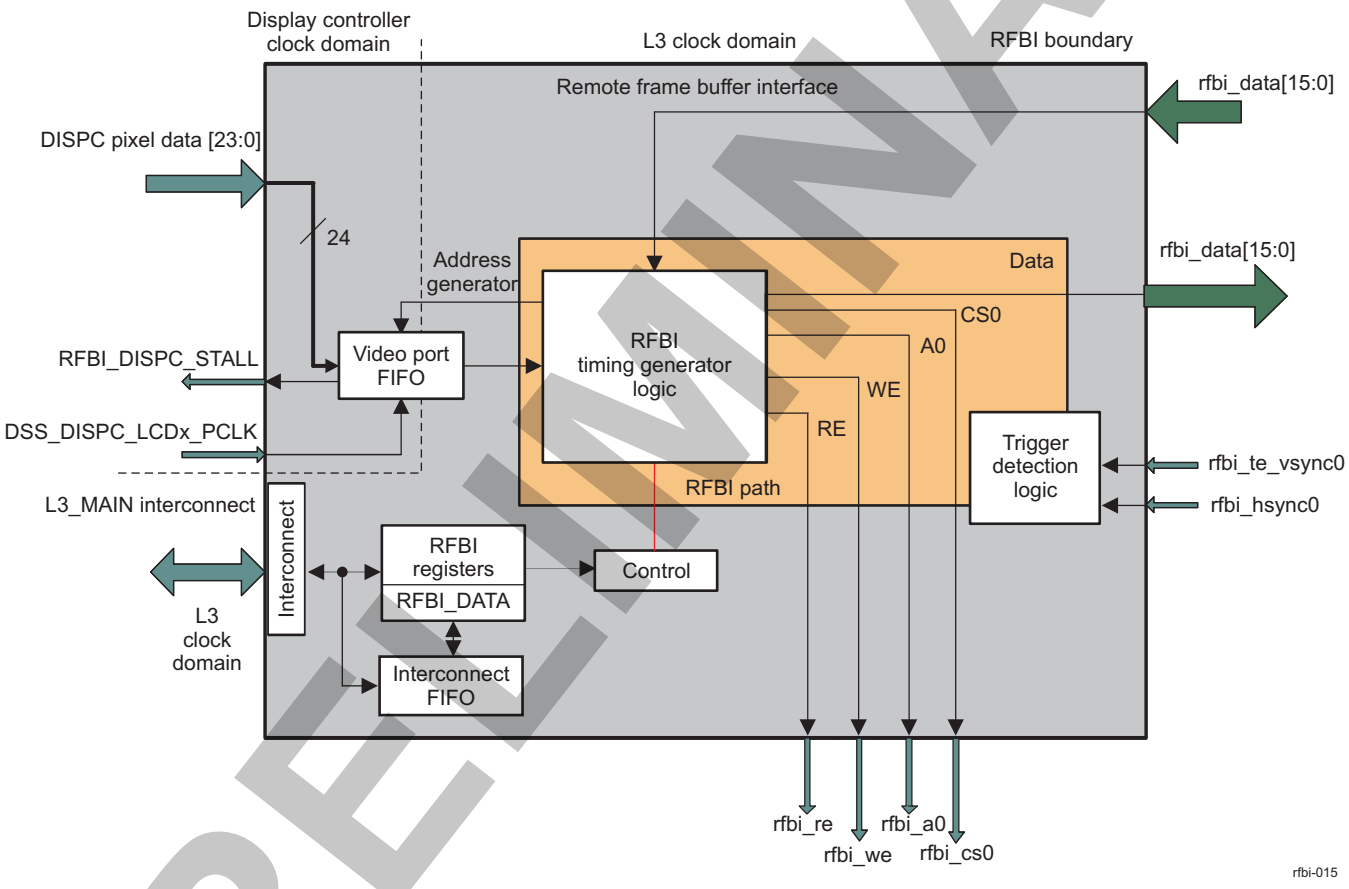
10.5.4.1 RFBI Block Diagram

The RFBI can capture the output pixel from the DISPC and send the data to the RFB in the LCD panel. The application configures the RFBI, sends commands, reads data, and configures the DISPC to send data fetched from the system memory by the DISPC DMA engine. The commands/data are sent using an 8-, 9-, 12- or 16-bit parallel interface.

The DISPC is configured to send the data in 12-, 16-, 18-, or 24-bpp format. In the video port FIFO, the encoded pixel values are in an LSB alignment independent of the endianness in system memory.

Figure 10-166 is an overview of the RFBI architecture.

Figure 10-166. RFBI Architecture Overview



10.5.4.2 RFBI Clock Configuration

The RFBI functional clocks (RFBI_FCLK1 and RFBI_FCLK2) are provided internally to the display subsystem by the DISPC. For more information about the DISPC clocks, see DISPC Clock Configuration, in *Display Controller*.

10.5.4.3 RFBI Software Reset

To perform a software reset, set the RFBI_SYSCONFIG[1] SOFTRESET bit to 1. The RFBI_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the RFBI_SYSCONFIG[1] SOFTRESET bit is automatically reset. Software must ensure that the software reset completes before performing any RFBI operation.

10.5.4.4 RFBI Power Management

Table 10-687 describes the power-management features available for the RFBI.

NOTE: For information about source clock gating description, see , *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 10-687. RFBI Local Power Management Features

Feature	Registers	Description
Clock autogating	RFBI_SYSCONFIG[0] AUTOIDLE bit	This bit allows a local power optimization inside the module by gating functional clocks (RFBI_FCLK1, RFBI_FCLK2) and interface clock (RFBI_ICLK) upon the internal activity.
Slave idle modes	RFBI_SYSCONFIG[4:3] SIDLEMODE bit field	Force-idle, no-idle, and smart-idle. For more information, see below.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

As shown in Table 10-687, the RFBI supports the no-idle, force-idle, and smart-idle modes.

The conditions of assertion of the SIdleAck signal are:

- No-idle mode: SIdleAck is never asserted.
- Force-idle mode: SIdleAck is asserted unconditionally after one RFBI_ICLK clock cycle delay with respect to assertion of IdleReq.
- Smart-idle mode: SIdleAck is asserted when the following conditions are satisfied: The RFBI stops using the RFBI_ICLK clock and all data have been sent to the RFB (LCD panel).

Once SIdleAck signal is asserted:

- The RFBI_ICLK (driven from DSS_L3_MAIN_ICLK) clock can shut down at any time.
- Any transaction on the RFBI configuration port is ignored

The conditions of deassertion of the SIdleAck signal are:

- Force-idle mode: SIdleAck is deasserted after one RFBI_ICLK clock cycle delay with respect to deassertion of IdleReq.
- Smart-idle mode: SIdleAck is deasserted after one RFBI_ICLK clock cycle delay with respect to deassertion of IdleReq.

Once SIdleAck is released, the RFBI is fully operational (guaranteed only in the case of the smart-idle mode).

10.5.4.5 RFBI Interrupt Requests

The RFBI does not generate interrupts but the following DISPC interrupts can be enabled depending on which LCD output of DISPC is currently used to connect to the RFBI:

- FRAMEDONE1_IRQ
- PROGRAMMEDLINENUMBER_IRQ
- GFXFIFOUNDERFLOW_IRQ
- GFXENDWINDOW_IRQ
- PALETTEGAMMALOADING_IRQ
- OCPERROR_IRQ
- VID1FIFOUNDERFLOW_IRQ

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

- VID1ENDWINDOW_IRQ
- VID2FIFOUNDERFLOW_IRQ
- VID2ENDWINDOW_IRQ
- SYNCLOST1_IRQ
- WAKEUP_IRQ
- SYNCLOST2_IRQ
- VID3FIFOUNDERFLOW_IRQ
- VID3ENDWINDOW_IRQ
- FRAMEDONE2_IRQ

NOTE: For more information about DISPC interrupts, see DISPC Overview, in Chapter 10,*Display Controller*.

The other DISPC interrupts are not used in the RFBI.

10.5.4.6 RFBI DMA Requests

Table 10-688 lists event flags and their mask that can cause RFBI DMA requests.

Table 10-688. RFBI DMA Requests Events

DMA Request Name	DMA Request Mask	Map to	Description
RFBI_DREQ	RFBI_CONTROL[7] DISABLE_DMA_REQ	DSS_SYSTEM_DREQ_13	DMA request used to transfer data using the DMA_SYSTEM from memory to the RFBI interconnect FIFO

NOTE: For more information about DMA requests, see Figure 10-173.

10.5.4.7 RFBI Video Port FIFO

10.5.4.7.1 RFBI Video Port Description

The input video port FIFO receives data from the DISPC at the pixel clock. The data in the video port FIFO are read by the RFBI and sent to the LCD panel. The video port FIFO is 24-bits wide and each pixel in 12-, 16-, 18-, and 24-bpp format is stored in the video port FIFO using one 24-bit value aligned on the 24-bit LSB. Section 10.5.4.9, *RFBI Output Parallel Modes*, provides examples of various output configurations based on the interface width (up to 16 bits) and pixel format output (up to 24 bits). Setting the RFBI_CONTROL[1] RFBIMODE bit to 0 directs the MPU to send commands, parameters, and data from the input video port FIFO.

10.5.4.7.2 RFBI Input Formats

The encoded pixel formats supported at the RFBI input interface connected to the DISPC are: RGB12-444, RGB16-565, RGB18-666, and RGB24-888. This input data width is controlled by the RFBI_CONFIG[6:5] DATATYPE bit field.

The following graphics describe the bit representation of each format in the video port FIFO. The output of the DISPC is aligned on the LSB of the interface. The pixels are then formatted in accordance with the configuration of the output interfaces (multiple cycles). For more information, see Section 10.5.4.9.1, *Cycle Mode Selection*.

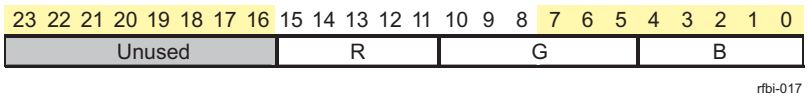
rfbi-016

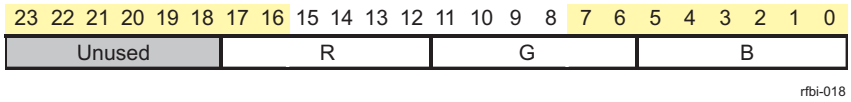
Copyright © 2013, Texas Instruments Incorporated

PRELIMINARY

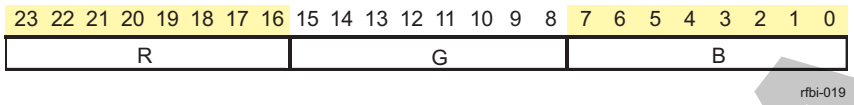
- RGB16-565 format:



- RGB18-666 format:



- RGB24-888 format:



NOTE: These pixel formats are also supported when data are provided from the slave port interconnect (for writing parameters).

10.5.4.7.3 RFBI Stall Mechanism

The stall signal (RFBI_DISPC_STALL) is generated by the video port FIFO to indicate when the DISPC must stop sending data on the corresponding LCD output interface. This stall signal is used for all three LCD outputs only when the DISPC is configured in stall mode. The stall mode is activated by setting the DISPC_CONTROLo[11] STALLMODE for the three LCD outputs.

NOTE: When the DISPC is configured in stall mode, the minimum transfer size is 1 byte.

The RFBI_DISPC_STALL signal allows the RFBI to reformat the data.

RFBI_DISPC_STALL is asserted when at least one of the following cases occurs:

- Default status when there is no data to capture from the DISPC
- High FIFO threshold reached
- End of transfer (number of data to output)
- RFBI reset
- RFBI_CONTROL[0] ENABLE bit reset to 0x0

RFBI_DISPC_STALL is deasserted when the RFBI_CONTROL[0] ENABLE bit is set to 0x1 and at least one of the following cases occurs:

- Low FIFO threshold reached
- External TE occurs and the RFBI_CONFIG[3:2] TRIGGERMODE bit field is set to 0x1 for automatic external trigger (start of the transfer, the FIFO pointers are reset, the FIFO is empty).
- RFBI_CONTROL[4] ITE bit set to 0x1 by users (start of transfer, the FIFO pointers are reset, the FIFO is empty)

NOTE: This stall mechanism is also used by the DSI protocol engines. When multiple modules are connected to the same LCD output (RFBI and DSI protocol engines), the STALL signals from the modules are merged into a single DSS_DISPC_LCDx_DATA_STALL signal inside the display subsystem. Only one signal for each LCD output is connected to the DISPC (three signals total for the three LCD outputs). In that case, only one module can control the STALL assertion/deassertion. The module that is not using the LCD output interface at that time is not disturbed because the STALL signal is asserted/deasserted by another module. For more information, see Chapter 10, *Display Subsystem* .

The RFBI asserts the STALL signal to stop data output by the DISPC. It is deasserted to indicate when new data must be output by the DISPC.

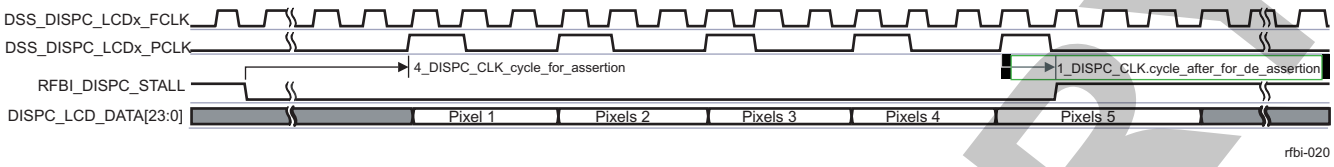
10.5.4.7.3.1 RFBI Data Stall Diagram Without DMA Buffer Handshake

Figure 10-167 shows the RFBI data stall diagram when the DISPC_DIVISOR[7:0] PCD bit field is set to 3.

Figure 10-167. RFBI Data Stall Signal Diagram With PCD = 3

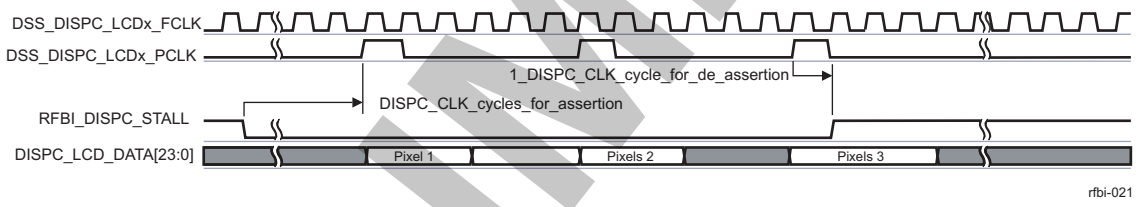


10.5.4.7.3.2 RFBI Data Stall Diagram With DMA Buffer Handshake

To avoid underflow of the DMA buffer, the DMA buffer handshake feature can be enabled by setting the DISPC_CONFIGo[16] BUFFERHANDCHECK bit to 1. The fullness of the FIFOs associated with the pipelines used for the LCD output is checked when the STALL signal is inactive before providing data to the pipeline. This prevents emptying the FIFO when the RFBI requests data and there is not enough data in the DISPC DMA buffer. This feature must be enabled only when the stall mode is used (DISPC_CONTROLo[11] STALLMODE bit set to 1).

When the DMA buffer handshake feature is activated, the pixel transfer to the RFBI during STALL inactivity period can be stopped (no DSS_DISPC_LCDx_PCLK pulse) and restarted when there is enough data in the DMA buffer. The DMA buffer handshake ensures that underflow cannot occur for the pipelines associated with the LCD output in stall mode. Figure 10-168 shows the RFBI data stall with the DMA buffer handshake mode activated (PCD = 3).

Figure 10-168. RFBI Data Stall Signal Diagram With Handshake With PCD = 3



10.5.4.8 RFBI Interconnect FIFO

10.5.4.8.1 RFBI Description

The interconnect FIFO receives the data from RFBI_DATA write requests to the slave port interconnect slave port. The data in the interconnect FIFO are read by the RFBI and sent to the LCD panel. The interconnect FIFO is 32-bits wide. The size of the interconnect FIFO is 24 words of 32 bits (that is, 24 words of RFBI_DATA). The address of the RFBI_DATA register is used to access the interconnect FIFO. The RFBI_DREQ DMA request can be used to transfer data using the DMA_SYSTEM from memory to the interconnect FIFO.

10.5.4.8.2 RFBI Using DMA Request With Interconnect FIFO

10.5.4.8.2.1 RFBI Threshold for DMA Request Generation

The RFBI_CONTROL[6:5] HIGHTHRESHOLD bit field defines the threshold to be used for the generation of the DMA request to receive data into the interconnect FIFO (24 × 32 FIFO depth) through the address of the register RFBI_DATA. The DMA_SYSTEM configuration regarding the size of the burst depends on the value of the RFBI_CONTROL[6:5] HIGHTHRESHOLD bit field. The supported values are 4 × 32, 8 × 32, and 16 × 32. For example, when 4 words of 32 bits are set for the threshold, the DMA_SYSTEM sends a burst of 4 × 32 bits only. The DMA_SYSTEM receives the DMA request and is in charge of providing the correct number of bytes.

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

10.5.4.8.2.2 RFBI Disabling DMA Request

If the RFBI_CONTROL[7] DISABLE_DMA_REQ bit is reset, the DMA request is generated when there is enough room in the interconnect FIFO to accept the full burst. In case the RFBI receives writes slave port requests to the RFBI_DATA location when the interconnect FIFO is full, the request is not accepted. The RFBI waits for a free entry in the interconnect FIFO to accept the slave port request.

If the RFBI_CONTROL[7] DISABLE_DMA_REQ bit is set, the DMA request is not generated and the threshold value is ignored.

NOTE: Software users can access the RFBI_DATA location without using the DMA request and without programming the high threshold value (backward compatibility mode).

10.5.4.8.2.3 RFBI Smart DMA Request Mode

If the RFBI_CONTROL[8] SMART_DMA_REQ bit is reset (smart DMA mode disabled), the DMA request is asserted and deasserted depending on the interconnect FIFO space even if MIdlereq is high in smart-idle/no-idle mode and the entire burst gets error responses from the RFBI. The RFBI waits for a free entry in the interconnect FIFO to accept the burst request.

If the RFBI_CONTROL[8] SMART_DMA_REQ bit is set (smart DMA mode enabled), the DMA request is deasserted after two RFBI_ICLK clock cycles, if it has been asserted for more than or equal to two RFBI_ICLK clock cycles and MIdlereq is high in smart-idle or no-idle mode. If asserting time is less than two RFBI_ICLK clock cycles, no more burst requests are accepted even if space is available in the interconnect FIFO.

10.5.4.9 RFBI Output Parallel Modes

10.5.4.9.1 RFBI Cycle Mode Selection

The RFBI_CONFIG[10:9] CYCLEFORMAT bit field defines the number of cycles to output a pixel. The number of cycles determines the number of registers used to format the data in the interconnect FIFO with the appropriate number of bits (starting from the LSB) and with the alignment on the interface. The data are formatted based on the configuration of the RFBI_DATA_CYCLEi registers.

- One cycle: RFBI_CONFIG[10:9] CYCLEFORMAT bit field = 0x00 and the RFBI_DATA_CYCLE1 register
- Two cycles: RFBI_CONFIG [10:9] CYCLEFORMAT bit field = 0x01 and the RFBI_DATA_CYCLE1 and RFBI_DATA_CYCLE2 registers
- Three cycles: RFBI_CONFIG[10:9] CYCLEFORMAT bit field = 0x10 and the RFBI_DATA_CYCLE1, RFBI_DATA_CYCLE2, and RFBI_DATA_CYCLE3 registers

Figure 10-169 through Figure 10-172 list the bits position of the pixel during the cycles for an 8-, 9-, and 16-bit parallel output, respectively.

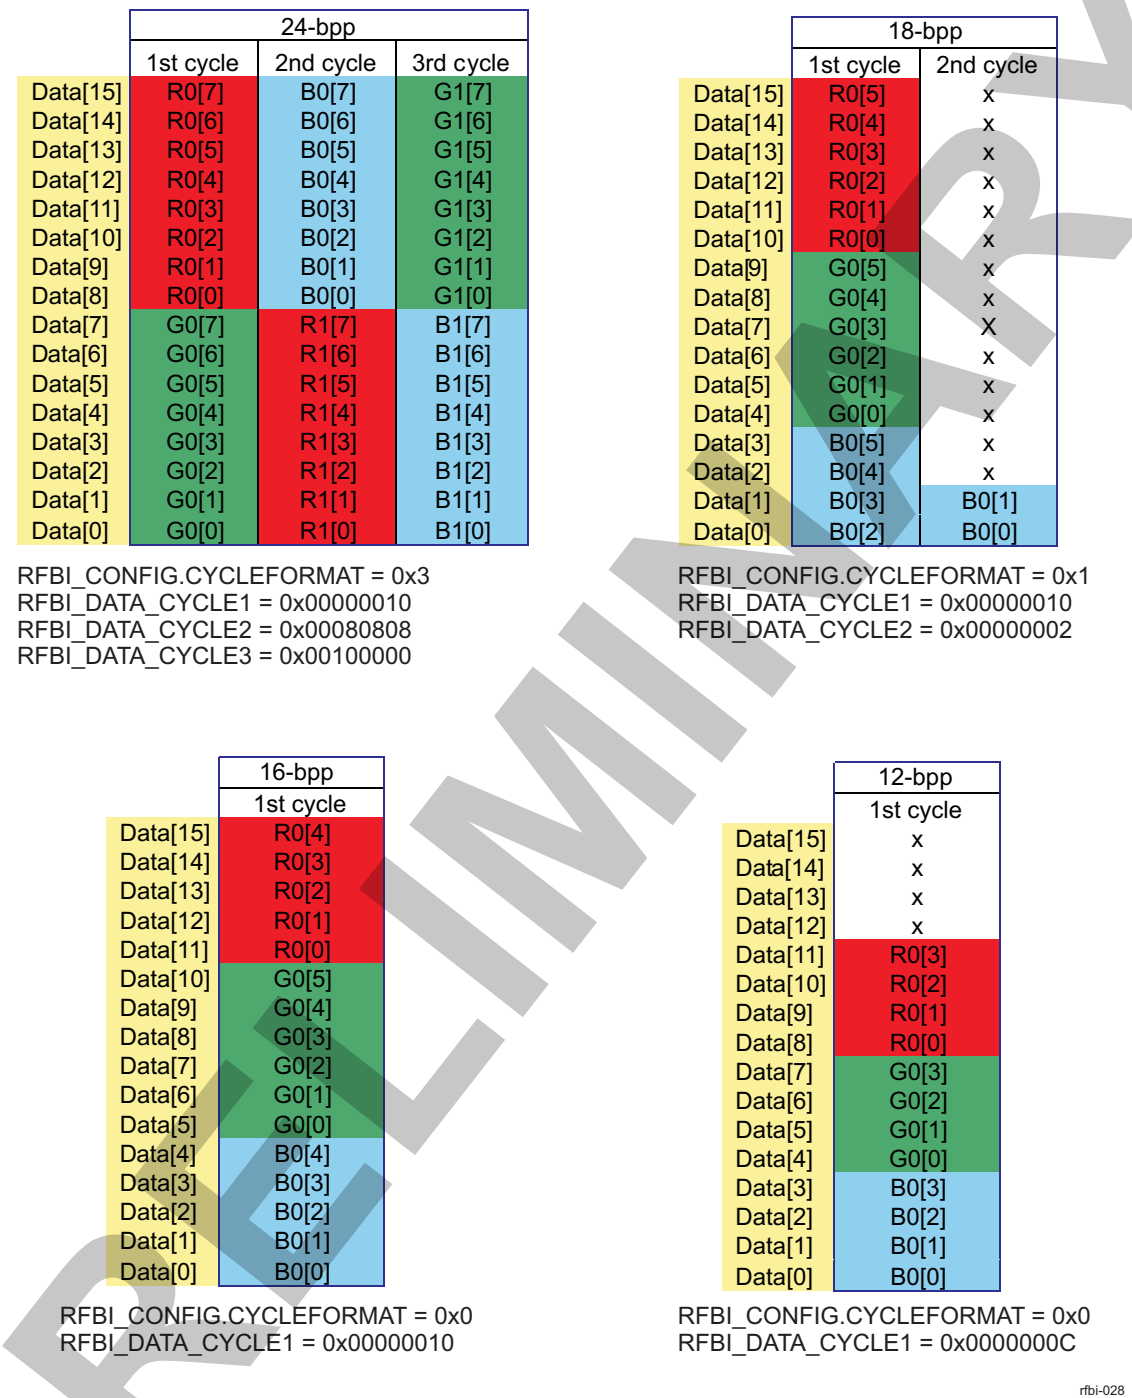
Figure 10-172. 16-Bit Interface Settings



10.5.4.9.2 RFBI Unmodified Bits

In a cycle, if every bit in the interface does not have a pixel value, the status of the unused bits can be programmed to be 0, 1, or the previous value (I/O power consumption optimization). Based on the configuration, the undefined bits for each cycle are defined with the previous values of the bits at the same position in the previous cycle, 0s, or 1s (the unused bits can be at any position). The RFBI_CONFIG[12:11] UNUSEDBITS bit field is used.

PRELIMINARY

10.5.4.9.3 RFBI Number of Pixels to Transfer

The RFBI_PIXEL_CNT[31:0] PIXELCNT bit field indicates the number of pixels to be transferred to the LCD panel. The value can be changed only when the RFBI_CONTROL[0] ENABLE bit is reset.

During the transfer, the hardware decrements the register when a pixel is sent to the RFB. When the RFBI_CONTROL[0] ENABLE bit is set and a new value is written in the RFBI_PIXEL_CNT register, and the current value in the register is a not 0 (the remaining number of pixels to transfer), the ongoing transfer is aborted.

10.5.4.10 RFBI Timing Generator

10.5.4.10.1 RFBI Configuration Selection

The RFBI_CONTROL[3:2] CONFIGSELECT bit field selects the chip-select.

10.5.4.10.2 RFBI Read/Write

Depending on the status of A0, WE, and RE, the commands and display/parameter data are written to the panel (handled by the state-machine for the commands/parameter data and stored in memory for the display data), or the display data/status values are read from the LCD panel (status and display data in the LCD panel memory). The polarity of A0 (RFBI_A0 signal), WE (RFBI_WE signal), RE (RFBI_RE signal), and CS0 (RFBI_CS0 signal) is programmable.

Table 10-689 describes the read/write function.

Table 10-689. RFBI Read/Write Function Description

A0 (RFBI_A0)	WE (RFBI_WE)	RE (RFBI_RE)	Function Description
1	0	1	Display data write, parameter data write
1	1	0	Display data read
0	1	0	Status read
0	0	1	Command data write

A minimum of RFBI_Cs cycle time, as defined in Table 10-690, is required to keep the RFBI_CS0 signal asserted between write transfers of multiple pixels.

Table 10-690 lists the minimum cycle time for RFBI_CS0, depending on the source of pixels (DISPC or slave port) and the cycle format (1pixel/cycle, 1 pixel/2 cycles, or 1 pixel/3 cycles).

Table 10-690. RFBI Minimum Cycle Time for CS0/WE Always Asserted

RFBI Performance	RFBI_CONFIG[10:9] CYCLEFORMAT	RFBI_CONFIG[8:7] PORTFORMAT	Minimum Cycle Time (in Number of RFBI_ICLK Clock Cycles)
Slave port interconnect	1 pixel/cycle	1 pixel	5
	1 pixel/2 cycles	1 pixel	4
	1 pixel/3 cycles	1 pixel	4
	1 pixel/cycle	2 pixels	4
	1 pixel/2 cycles	2 pixels	4
	1 pixel/3 cycles	2 pixels	4
DISPC	1 pixel/cycle	N/A	4
	1 pixel/2 cycles	N/A	3
	1 pixel/3 cycles	N/A	3
	2 pixel/3 cycles	N/A	6

PRELIMINARY

10.5.4.10.3 RFBI State-Machine

The RFBI_A0, RFBI_RE, and RFBI_WE signals are asserted and deasserted based on the register accessed (RFBI_CMD, RFBI_PARAM, RFBI_DATA, RFBI_READ, or RFBI_STATUS). (See Table 10-689.) When the RFBI_SYSSTATUS[8] BUSY bit is set by hardware, any access to the registers is stalled, except for the RFBI_DATA register.

The RFBI_SYSSTATUS[9] BUSYRFBIDATA bit indicates whether there are still pending data in the interconnect FIFO associated with the RFBI_DATA register only.

- Command register

  Write one command at a time by writing through the slave port interconnect into the RFBI_CMD register. If the previous command is not processed, the RFBI_SYSSTATUS[8] BUSY bit is set by hardware and access to writing a new command is stalled.

- Parameter register

  Write one parameter at a time by writing in the RFBI_PARAM register.

  If the previous parameter is not processed, the RFBI_SYSSTATUS[8] BUSY bit is set by hardware and access to writing a new parameter is stalled.

- Data register

  Write one or two pixels at a time by writing in the RFBI_DATA register.

  The pixels are formatted based on the specified cycle format. If two pixels are written into the 32-data register, the RFBI_CONFIG[8:7] PORTFORMAT bit field indicates the number of pixels for each slave port access to the register and the order of the pixels.

  If the previous data are not processed, the RFBI_SYSSTATUS[8] BUSY bit is set by hardware and any access for writing new data is stalled. When the RFBI_SYSSTATUS[8] BUSY bit is reset by hardware, access is not stalled.

- Read/status register

  Send through the command and parameter registers the correct information to receive data in the data or status register. The read data from the LCD panel is initiated by writing into the RFBI_READ or RFBI_STATUS registers. In this case, the RFBI_SYSSTATUS[8] BUSY bit is set until the data are available in the register.

  When the RFBI_SYSSTATUS[8] BUSY bit is set by hardware, the read or write access is stalled until the register is updated with a new value from the LCD panel. To avoid the stall, the software can poll the RFBI_SYSSTATUS[8] BUSY bit until it is reset by hardware. To receive the data, send the appropriate command/parameters.

10.5.4.10.4 RFBI Timings

The timing registers can be accessed only when there is no transaction in progress (based on the value of the RFBI_CONTROL[3:2] CONFIGSELECT bit field). Granularity is defined using the RFBI_CONFIG[4] TIMEGRANULARITY bit. This feature allows the extension of programmable ranges of timing parameters for the RFBI interface. See Table 10-691 for the configuration values of the timing bits.

- Chip-select assertion/deassertion time (CSOnTime/CSOffTime)

  RFBI_A0 setup time to chip-select assertion is assured by the programmable chip-select assertion time from the start access time:
  RFBI_ONOFF_TIME[3:0] CSONTIME bit field

  The chip-select deassertion time from the start access time is programmable:
  RFBI_ONOFF_TIME[9:4] CSOFFTIME bit field

CAUTION

Configuring RFBI_ONOFF_TIME[3:0] CSONTIME = RFBI_ONOFF_TIME[9:4] CSOFFTIME = 0 is not supported and must be avoided. This configuration creates contention on the bus and progressively damages the LCD panel.

- Chip-select pulse width (CSPulseWidth)

Copyright © 2013, Texas Instruments Incorporated
PRELIMINARY

The total chip-select pulse width is the time when write cycle time or read cycle time completes and is programmable:
RFBI_CYCLE_TIME[17:12] CSPULSEWIDTH bit field

It applies on the read-to-write, write-to-read, read-to-read, and write-to-write access based on:

– The RFBI_CYCLE_TIME[19] RRENABLE bit: Read-to-read access
– The RFBI_CYCLE_TIME[20] WWENABLE bit: Write-to-write access
– The RFBI_CYCLE_TIME[18] RWENABLE bit: Read-to-write access
– The RFBI_CYCLE_TIME[21] WRENABLE bit: Write-to-read access

By default, it applies to any access (read-to-read, read-to-write, write-to-read, write-to-write) when the chip-select CS0 is activated by setting the RFBI_CONTROL[3:2] CONFIGSELECT bit field to 0x1.

- Access time

  Access time is the time delay between A0 assertion to data sampling before RE signal deassertion; access time is programmable:
  RFBI_CYCLE_TIME[27:22] ACCESSTIME bit field

  When reading the data on the bus, the data are sampled at the end of the access time, which occurs before the end of the read off time (RFBI_ONOFF_TIME[29:24] REOFFTIME).

- Write-enable cycle time (WECycleTime)

  The total write-enable cycle time is the time when A0 becomes valid until write cycle completion; the write-enable cycle time is programmable:
  The RFBI_CYCLE_TIME[5:0] WECYCLETIME bit field

- Write-enable assertion/deassertion time (WEOnTime/WEOffTime)

  The WE assertion delay time from start access time is programmable:
  RFBI_ONOFF_TIME[13:10] WEONTIME bit field

  The WE deassertion delay time from the start access time is programmable:
  RFBI_ONOFF_TIME[19:14] WEOFFTIME bit field

- Read-enable cycle time (RECycleTime)

  The total read-enable cycle time is the time when A0 becomes valid until read cycle completion; the read-enable cycle time is programmable:
  The RFBI_CYCLE_TIME[11:6] RECYCLETIME bit field

- Read-enable assertion/deassertion time (REOnTime/REOffTime)

  The RE assertion delay time from the start access time is programmable:
  RFBI_ONOFF_TIME[23:20] REONTIME bit field

  The RE deassertion delay time from the start access time is programmable:
  RFBI_ONOFF_TIME[29:24] REOFFTIME bit field

At cycle time completion (read access or write access), all control signals (RFBI_CS0, RFBI_WE, and RFBI_RE) are deasserted regardless of their deassertion time parameter values, if they are not deasserted already.

However, an exception to this forced deassertion exists when a pipelined request to CS0 is pending. Also, a control signal with deassertion time parameters equal to the cycle time parameter is not necessarily deasserted when a pipelined request to the same chip-select or different chip-select is pending. This prevents any unnecessary glitch transitions.

If no inactive cycles are required between successive accesses to the same chip-select (the RFBI_CYCLE_TIME[17:12] CSPULSEWIDTH bit field = 0), and if assertion time parameters associated with the following access equal 0, the asserted control signals (RFBI_CS0, RFBI_WE, and RFBI_RE) stay asserted. This applies only to write-to-write access combination. In case of read-to-write, read-to-read, or write-to-read sequences, the RFBI_CS0, RFBI_WE, and RFBI_RE signals are always deasserted.

Table 10-691 lists the configuration values for each timing bit.

Table 10-691. RFBI Timings Configuration

Timing Configuration Bits	Granularity[1]	
	One	Two
RFBI_ONOFF_TIME[3:0] CSONTIME	0 to 15	0 to 30
RFBI_ONOFF_TIME[9:4] CSOFFTIME	0 to 63	0 to 126
RFBI_CYCLE_TIME[17:12] CSPULSEWIDTH	0 to 63	0 to 126
RFBI_CYCLE_TIME[27:22] ACCESSTIME	0 to 63	0 to 126
RFBI_CYCLE_TIME[5:0] WECYCLETIME	0 to 63	0 to 126
RFBI_ONOFF_TIME[13:10] WEONTIME	0 to 15	0 to 30
RFBI_ONOFF_TIME[19:14] WEOFFTIME	0 to 63	0 to 126
RFBI_CYCLE_TIME[11:6] RECYCLETIME	0 to 63	0 to 126
RFBI_ONOFF_TIME[23:20] REONTIME	0 to 15	0 to 30
RFBI_ONOFF_TIME[29:24] REOFFTIME	0 to 63	0 to 126

(1) Number of RFBI_ICLK clock cycles. The granularity can be configured using the RFBI_CONFIG[4] TIMEGRANULARITY bit.

10.5.4.11 RFBI Trigger Detection Logic

10.5.4.11.1 RFBI Trigger Mode

Setting the RFBI_CONFIG[3:2] TRIGGERMODE bit field configures the different trigger modes:

- Internal trigger mode with the internal programmable RFBI_CONTROL[4] ITE bit
- External trigger mode with the external TE signal (RFBI_TE_VSYNC)
- External trigger mode with the external VSYNC/HSYNC signals

10.5.4.11.2 RFBI Internal Trigger Mode

10.5.4.11.2.1 RFBI ITE Bit

Set the RFBI_CONTROL[4] ITE bit to start capturing the data from the DISPC. The DISPC must be configured in the RFBI mode to account for the RFBI_DISPC_STALL signal. Setting the trigger mode to external (RFBI_CONFIG[3:2] TRIGGERMODE bit field set to 0x1 or 0x2) causes the RFBI_CONTROL[4] ITE bit to be ignored. The chip-select CS0 must be selected (RFBI_CONTROL[3:2] CONFIGSELECT set to 0x1) when this bit is set by users.

10.5.4.11.3 RFBI External Trigger Mode

There are two external trigger modes:

- TE only: VSYNC and HSYNC are merged by logical OR operation and are detected through VSYNC and HSYNC pulse widths.
- HSYNC/VSYNC: This mode uses the two external signals, which are detected through VSYNC and HSYNC pulse widths.

10.5.4.11.3.1 RFBI Programmable Line Number

When the trigger mode is set to external trigger mode with HSYNC and VSYNC or the TE, hardware resets the line counter when the VSYNC occurs and, after a programmable number of lines programmed by the user in the RFBI_LINE_NUMBER[10:0] LINENUMBER bit field (the HSYNC pulse occurs for every line), the transfer to the LCD panel begins. When the programmable line number is 0, only the VSYNC pulse indicates the beginning of the transfer in both modes: HSYNC/VSYNC and TE (logical OR operation between HSYNC and VSYNC).

PRELIMINARY

Copyright © 2013, Texas Instruments Incorporated

10.5.4.11.3.2 RFBI VSYNC Pulse Width (Minimum Value)

The RFBI_VSYNC_WIDTH[15:0] MINVSYNCPULSEWIDTH bit field defines the minimum number of RFBI_ICLK clock cycles of the VSYNC pulse for detection on VSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal, and is also used in HSYNC/VSYNC mode on the two separate input lines.

- The VSYNC pulse width must be equal to at least two RFBI_ICLK clock cycles when HSYNC is not present (TE trigger mode only).
- The VSYNC pulse width must be equal to at least four RFBI_ICLK clock cycles when HSYNC is present (TE trigger mode only).

10.5.4.11.3.3 RFBI HSYNC Pulse Width (Minimum Value)

The RFBI_HSYNC_WIDTH[15:0] MINHSYNCPULSEWIDTH bit field defines the minimum number of RFBI_ICLK clock cycles of the HSYNC pulse for detection on HSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal, and is also used in VSYNC/HSYNC mode on the separate two input lines. To be detected, the HSYNC/VSYNC pulse width must always be equal to at least two RFBI_ICLK clock cycles. See Table 10-692.

Table 10-692. RFBI Minimum Pulse Width (HSYNC/VSYNC)

Configuration Bits	TE Mode	HSYNC/VSYNC Mode
RFBI_HSYNC_WIDTH[15:0] MINHSYNCPULSEWIDTH field value	2	2
RFBI_VSYNC_WIDTH[15:0] MINVSYNCPULSEWIDTH field value	4	2

The pulse received by the RFBI must be at least two RFBI_ICLK clock cycles to be detected. For the TE mode, since the minimum value to differentiate VSYNC and HSYNC is two RFBI_ICLK clock cycles, the VSYNC pulse width must be at least four RFBI_ICLK clock cycles and the HSYNC pulse width must be at least two RFBI_ICLK clock cycles.

10.5.5 RFBI Programming Guide

10.5.5.1 RFBI Low-Level Programming Models

This section covers the low-level hardware programming sequences for configuration and use of the RFBI.

10.5.5.1.1 RFBI Global Initialization

10.5.5.1.1.1 RFBI Surrounding Modules Global Initialization

This section identifies the requirements to initialize the surrounding modules when the RFBI is to be used for the first time after a device reset. This initialization of the surrounding modules is based on the integration and environment of the RFBI. For more information, see Section 10.5.2, *RFBI Environment*, and Section 10.5.3, *RFBI Integration*.

Table 10-693 describes the global initialization of surrounding modules.

Table 10-693. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	RFBI_ICLK interface clock must be enabled. For more information, see , *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
DISPC	RFBI_FCLK1 and RFBI_FCLK2 functional clocks must be enabled (see Section 10.2.1, DISPC Overview).
Control module	rfbi_re pad muxing must be set in the SYSCTRL_PADCONF_CORE module. rfbi_we pad muxing must be set in the SYSCTRL_PADCONF_CORE module. rfbi_cs0 pad muxing must be set in the SYSCTRL_PADCONF_CORE module. rfbi_te_vsync0 pad muxing must be set in the SYSCTRL_PADCONF_CORE module. rfbi_data[15:0] pads muxing must be set in the SYSCTRL_PADCONF_CORE module. rfbi_hsync0 pad muxing must be set in the SYSCTRL_PADCONF_CORE module. rfbi_a0 pad muxing must be set in the SYSCTRL_PADCONF_CORE module. For more information, see , *Pad Functional Multiplexing and Configuration*, in *Chapter 18, Control Module*.
MPU INTC	MPU interrupt controller configuration must be done to enable the interrupts from the DISPC module. For more information, see , *Interrupt Controllers Overview*, in *Chapter 17, Interrupt Controllers*.
DMA_SYSTEM	DMA configuration must be done to enable the RFBI module DMA channel requests. For more information, see , *DMA_SYSTEM Module Overview*, in Chapter 16*System DMA*.
Interconnect	For more information about the interconnect configuration, see , *L3 Interconnect*, in *Chapter 14, Interconnects*.

NOTE: The MPU INTC and the DMA_SYSTEM configurations are necessary if the interrupt- and DMA-based communication modes are used.

10.5.5.1.1.2 RFBI Global Initialization

10.5.5.1.1.2.1 RFBI Main Sequence RFBI Global Initialization

This procedure initializes the RFB and DISPC after a power on or software reset (see Table 10-694).

Table 10-694. RFBI Global Initialization

Step	Register/Bit Field Programming Model	Value
DISPC configuration in RFBI mode	See Section 10.5.5.1.1.2.2, *Subsequence: DISPC Configuration.*	
RFBI configuration	See Section 10.5.5.1.1.2.3, *Subsequence: RFBI Configuration.*	
LCD panel configuration	See Section 10.5.5.1.1.2.4, *Subsequence: LCD Panel Configuration*.	

10.5.5.1.1.2.2 RFBI Subsequence: DISPC Configuration

This procedure configures the DISPC registers in RFBI mode (see Table 10-695).

Table 10-695. RFBI DISPC Configuration in RFBI Mode

Step	Register/Bit Field Programming Model	Value
DISPC pipeline configuration	Configuration of the pipeline associated with the LCD output, such as the DMA engine and pipelines associated with the LCD output (see DISPC Overview, in *Display Controller*).	
Enable TFT mode.	DISPC_CONTROLo[3] STNTFT	0x1
Program the DISPC in RFBI mode.	DISPC_CONTROLo[11] STALLMODE	0x1
Reset the DISPC signal configuration to default value.	DISPC_POL_FREQo	0x00
Select the RFBI data path.	DISPC_CONTROL1[16:15] GPOUT	0x1
Enable the hardware handshake to avoid the DISPC FIFO underflow (applies to the pipeline connected to the LCD output).	DISPC_CONFIGo[16] BUFFERHANDCHECK	0x1

NOTE: In RFBI mode, the DISPC_CONTROLo[5] GOLCD bit must not be set to 1. It must be disabled before resetting the DISPC_CONTROLo[11] STALLMODE bit to 0.

The hardware handshake applies to the pipelines connected to the LCD output. It must be disabled before resetting the DISPC_CONTROLo[11] STALLMODE bit to 0.

10.5.5.1.1.2.3 RFBI Subsequence: RFBI Configuration

This procedure configures the RFBI registers. See Table 10-696.

CAUTION

The RFBI configuration registers for CS0 configuration can be accessed only when the configuration is not in use (that is, when the RFBI_CONTROL[3:2] CONFIGSELECT is set to 0x0).

Table 10-696. RFBI Configuration – Main Sequence

Step	Register/Bit Field Programming Model	Value
Enable the RFBI data path.	RFBI_CONTROL[1] RFBIMODE	0x0
DMA mode configuration	See Section 10.5.5.1.1.2.3.1, *Subsequence: DMA Mode Configuration.*

Enable the DISPC output.	DISPC_CONTROLo[0] LCDENABLE	0x1

10.5.5.1.2.1.5 RFBI Subsequence: RFBI Output Enable

This procedure enables the RFBI output. Figure 10-175 details the settings for this subsequence.

Figure 10-175. RFBI Output Enable Flow Chart

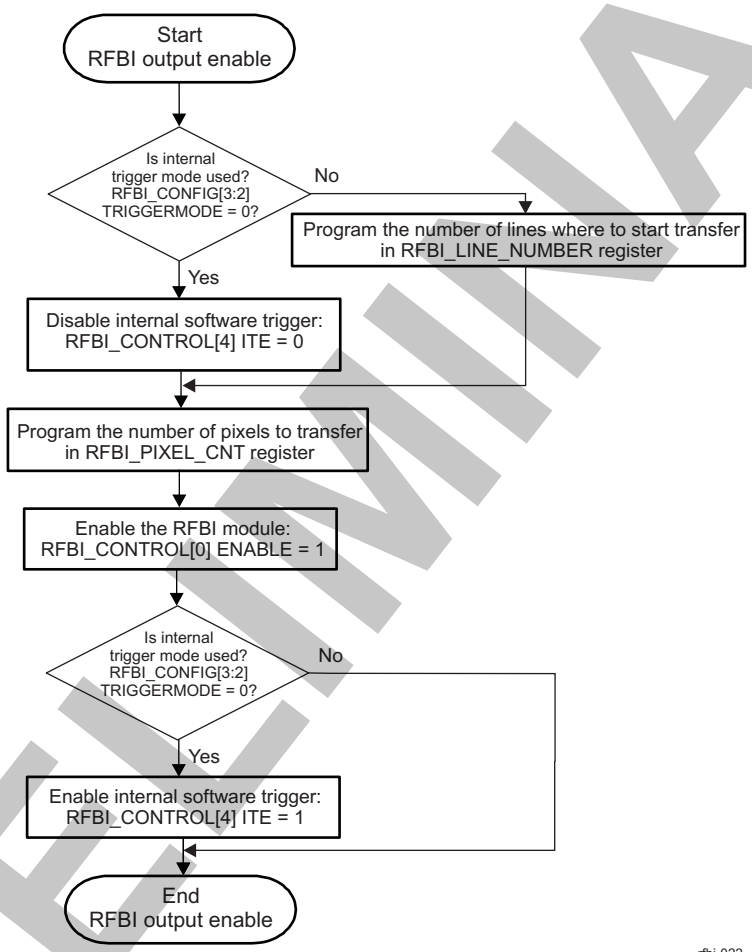

Table 10-706 describes the RFBI output enable.

Table 10-706. Register Call Summary for Subsequence: RFBI Output Enable

Register Name		
RFBI_CONFIG	RFBI_CONTROL	RFBI_LINE_NUMBER
RFBI_PIXEL_CNT		

Table 10-707 describes the RFBI behavior depending on the RFBI output enable.

PRELIMINARY

Table 10-707. RFBI Behavior

RFBI_CONTROL[0] ENABLE Bit Value	RFBI Behavior
0	Slave port interconnect can write command/parameter/data and read data/status from the RFB. Slave port interconnect access can only be done to the active CS0.
1	The DISPC sends pixels to the RFB.

NOTE: The LCD output is disabled at the end of the transfer of the frame. The software must reenable the LCD output to generate a new frame by setting the DISPC_CONTROLo[0] LCDENABLE bit to 1.

CAUTION

The following registers must not be modified when the module is enabled (the RFBI_CONTROL[0] ENABLE bit is set to 1):

- RFBI_CONTROL
- RFBI_PIXEL_CNT
- RFBI_LINE_NUMBER
- RFBI_STATUS
- RFBI_CONFIG
- RFBI_ONOFF_TIME
- RFBI_CYCLE_TIME
- RFBI_DATA_CYCLEi (i = 1 to 3)
- RFBI_VSYNC_WIDTH
- RFBI_HSYNC_WIDTH

NOTE: The RFBI_DISPC_STALL signal is asserted when the RFBI is disabled. Pixels can be sent to the LCD panel through the slave port only when the pixel count has reached 0x0.

10.5.5.1.2.1.6 RFBI Subsequence: Detect Event

Table 10-708 describes the detect event.

Table 10-708. RFBI Detect Event

Step	Register/Bit Field Programming Model	Value
Wait until DISPC_IRQSTATUS != 0.	DISPC_IRQSTATUS	
Service event	See Section 10.5.5.1.3, *RFBI Events Servicing*.

10.5.5.1.3 RFBI Events Servicing

10.5.5.1.3.1 RFBI FRAMEDONE Interrupt Servicing

The FRAMEDONE event occurs each time a frame is transferred to the LCD panel. Figure 10-176 details how to serve this event.

Figure 10-176. RFBI FRAMEDONE Event Servicing Flow Chart

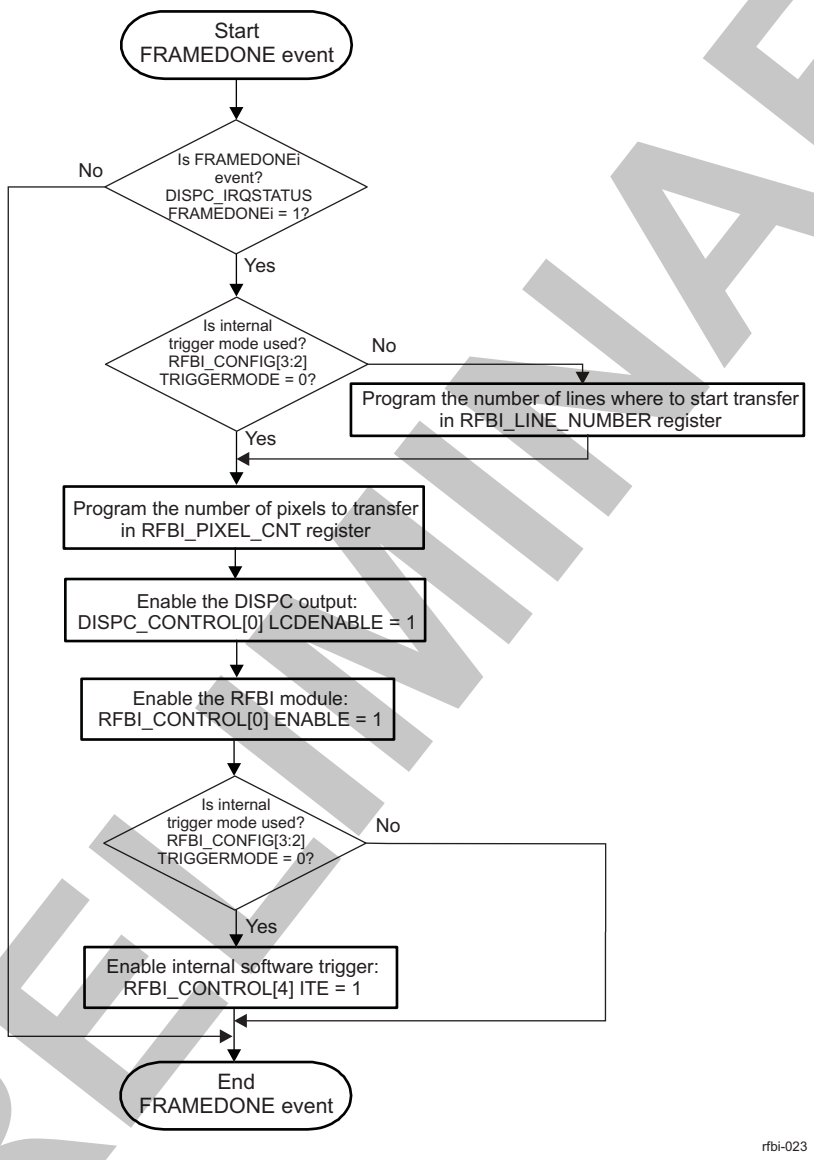

Table 10-709 describes FRAMEDONE interrupt servicing.

Table 10-709. Register Call Summary for RFBI Events Servicing: FRAMEDONE Interrupt Servicing

10.5.6 RFBI Hardware Status Features

Table 10-710 lists the RFBI hardware status features.

Table 10-710. RFBI Hardware Status Features

Feature	Type	Register/Bit Field/Observability Control	Description
Data pending	Status	RFBI_SYSTATUS[9] BUSYRFBIDATA	It is set to 1 when some data are pending to be processed from the interconnect FIFO.
Slave port bus busy	Status	RFBI_SYSTATUS[9] BUSY	It is set to 1 when the slave port bus is busy and access to some RFBI registers (RFBI_CMD, RFBI_STATUS, RFBI_PARAM, and RFBI_READ) is stalled.
